A

Aarons, Dr. S. J., Gynecological Therapeutics, 1910 (review), 588
Abbé, Dr. R., surgical resection of posterior spinal roots, 896
Abbey Sanatorium, Belfast, 62
Abbott, Mr. T. K., a Latin treatise, 57
Abbott *v.* Ryall, report of case, with issue, 185, 190
Abderhalden, Dr. E., Fortschritte der Naturwissenschaftlichen Forschung, 1911 (review), 1140
Abdomen, cysts of, improved drainage-tube for, 1016; tumour of, in girl, aged 2½ years, case for diagnosis, 507; wall of, actinomycosis of, 163
Abdominal cases, gastro-mesenteric ileus as post-operative complication in, 810; lesions, acute, commoner, surgery of, 1208; Operation, Extended, in Cancer of Neck of Uterus based upon 500 Cases (Die Erweiterte Abdominale Operation bei Carcinoma Colli Uteri auf Grund von 500 Fälle (Prof. E. Wertheim) (review), 1356; Operations on Pelvic Organs, After-results of, Study of, based on 1000 Consecutive Cases) (Dr. A. E. Giles) (review), 310; respiratory movements, absence of, as indication of pericarditis, 302; symptoms, acute, some of more rare causes of (Mr. W. H. Battle), 6; wall, eruption of favus on, in female child, 103
Aberdeen, city of, annual report of medical officer of health, 963; county of, health report for, 1389; Hospital Sunday in, 198; medical inspection in, increased cleanliness of the children, 623; of school children in, 268; tuberculosis in, 623; tuberculosis and occupation in, 770; University of, abuse of Carnegie Trust at, 1234; pass-lists, 1043; vaccination in, interesting figures, 623
Aberdeen Dispensary, serious financial situation, 770
Aberdeen district committee and vaccination, 1235
Aberdeen Poorhouse, medical officer appointed to, 545
Aberdeen Royal Infirmary and Lunatic Asylum, annual meeting, 474
Aberdeen students, decision regarding injury to Mr. Asquith's carriage, 338
Aberdeen, University of, bequest to, 1677
Aberystwith health report, 843
Aberystwith Infirmary, 472
Abnormalities, bodily, voluntary production of, 408
Aboriginal, Australia, and Tasmanian, physical anthropology of, 1150
Abortion, criminal, conviction of a medical man, 775; habitual, and potassium chlorate, 1222; pathology of, embryo in relation to, 444
Abraham, Dr. P. S., case of mycosis fungoides, 1207; discussion on the present position of vaccine-therapy, 743; discussion on some pharmacological effects of the strong sulphur water (Harrogate), 1206
Abrahams (see Markhams *v.* Abrahams)
Absorption-time for serums, 489
Accessory Sinuses, Nasal Diseases of (Dr. G. Wyllie) (review), 1506
Accident hospital, new, at Garston, 268
Accidents to workmen, medical treatment of, 270
Accidents (see also Street accidents)
Accommodation, anatomical and mechanical factors in, 1702
Accounts of medical men (leading article), 176
Acidosis, 504; relation of acute phosphorus poisoning to (Dr. H. L. Tidy), 19
Ackland, Mr. D., oral sepsis, 28
Acland, Dr. T. D., appointment to, 184
Aconite, poisoning by (Dr. T. Inglis), 162
Acromegalic crania, resemblance to Neanderthaloid, 993
Acromegaly as atavistic manifestation, 993; changes of skull in, 999; growth changes in anthropoids compared with those seen in, 998; head and skull in, 1002; mandible, 996; in other parts and systems of body in, 1001; in palate in, 995; material for study in London, 995; pathological changes in, 1670; skeletal changes in, inquiry into nature of (Dr. A. Keith), 993; skeleton of subject who had suffered from, 882; in young girl aged 15 years, 507
Actinomycosis, 407; of abdominal wall, 163; of brain and meninges, 1592
Action and emotion, clinical aspects of (Dr. T. C. Shaw), 353, 356; treatment, 356
Adam, Dr. C., Handbook of Treatment for Diseases of the Eye (Ophthalmic Therapeutics), 1911 (review), 1706
Adami, Prof. J. G., elected president of the Association of American Physicians, 1620
Adams, Dr. E. W., discussion on cases of injury under Workmen's Compensation Act, 509; National Insurance Bill, 1605
Adams, Mr. J. E., consideration of some cases of advanced tubercular joints treated by ileo-colostomy, 1306
Adamson, Mr., discussion on peritoneal lesions, 810
Addison, Mr. O. L., case of syphilitic osteomyelitis of the humerus and tibia, 1208; case of tubercle of the epiphysis of the head of the femur, 1208; malformation of the femur in a child, 1206
Adelaide Hospital, 1614
Adeno-carcinoma (keratinising) of uterus, removal, 27; of common bile-duct, 1078
Adenoids associated with albuminuria and casts, removal of adenoids followed by disappearance of urinary changes (Dr. J. M. O'Meara), 1204
Adenoma vaginæ, case of, 1424
Adenoma vaginæ diffusum (adenomatosis vaginæ, 1425
Adenomyoma, localised, in tuberculous Fallopian tube, removal, 27
Adhesions, treatment of, in appendicectomy, 811
Admiralty, action towards Naval Medical Department ("Why?") 58
Adnexa, importance of removing uterus in certain diseased conditions of (Dr. J. M. Munro Kerr), 95
Adolescence, albuminuria occurring in, after-history of cases, 1134, 1205
Adrenal glands, tumours of, 305
Adrenalin, action of, 1610; treatment of malignant growths by, 199
Adrenine, question of, as term of nomenclature, 73
Adulteration of bread (Parliamentary question), 479, 1110
Adults, mortality of, in France, 624
Æsculape (review), 592
Affleck, Dr. J. O., discussion on duodenal ulcer, 740
Africa, East, Protectorate of, climatic and health conditions of, 980
Africa, South, Correspondence from.—Public health matters, 66—Death of Dr. John Greathead; Medical education, 67—Health department for South Africa; Segregation of lepers, 342—Memorial to the late King,

(RECAP) WZ 8950 .558 1911 v.1 pt.1 707400

343—Black peril, 908—Employment of European nurses in native wards; Orange River Colony Medical and Pharmacy Board, 973—Public Health Bill, 974—Hospitals and the insane; Miners' phthisis legislation; Medical inspection and research into diseases prevalent in mines; Public Health Bill; Immigration Bill; Anatomy Bill; Post-graduate classes, 1239, 1240—Parliamentary session; Miners' Phthisis Bill; Labour recruiting; Bacteriological research laboratory for South Africa; Medical men and the lay press; Death of a well-known South African practitioner, 1539, 1540

Africa, West, Hygiene and Fevers of (Mr. E. F. Grune) (review), 515; yellow fever in, 1173
After-care Association (leading article), 455; for recovered insane, annual meeting, 477
Age, influence of, on pressor bases of urine, 1409
Agglutination methods in diagnosis of plague, 1382
Agglutination tests, diagnosis of plague, 1311
Agglutinins, transmission of, through placenta and mammary gland (Dr W. J. Wilson and Dr. J. A. Sinton), 1002
Aikin, Dr. W. A., The Voice, an Introduction to Practical Phonology, 1910 (review), 1012
Air, compressed, and caisson sickness, 824; rupture of large intestine due to, 524
Air-passages, foreign bodies removed from, 1423; lower, removal of foreign bodies impacted in, by direct bronchoscopy (Mr. H. Tilley), 1066
Air, vitiated, measurement of in confined spaces, 1613
Airedale, Lord, death of, 821
Aitken, Dr. C., solid glycerine-gelatine tampons, 1457
Albinism in Man, Monograph on (Mr. K. Pearson and others) (review), 942
Albulactin, 34
Albumin, assimilation of, physiology and pathology of (Dr. S. A. Arany), 502
Albuminuria, adenoids associated with, disappearance of urinary changes on removal of adenoids (Dr. J. M. O'Meara), 1204; dropsy, chyliform ascites and syphilis, case of, 439; occurring in adolescence, after-history of cases, 1134, 1205; physiological (leading article), 1364
Alcock, Dr. H. N., appointment of professorship, 1223
Alcohol, injection of, in case of trigeminal neuralgia, 28; two cases of trigeminal neuralgia cured by, 507
Alcohol in chocolates, 1232
Alcoholism, parental, influence of on physique and ability of offspring (Dr. T. B. Hyslop), 77, 118, 164
Alcoholism and insanity, 1252
Alderson, Dr. R., discussion on general anæsthetics, 743
Alderton, Mr. T. G., presentation to, 279
Alexander, Dr. D. M., three cases of infection by bacillus aerogenes capsulatus, 445; and Crawford, Mr. D., specimens of primary and of secondary tubercle of tongue, 445
Alexander, Dr. W., puerperal convulsions, or eclampsia, at the Liverpool Workhouse Hospital, 217
Alexandra Hospital, Montreal, annual meeting, 1175
Algeria, notification of infectious diseases in, 132
Aliens and disease (Parliamentary question), 912; indigent, and public health, 1147; and pistols, 894; and trachoma, 1298; (Parliamentary question), 1111, 1181; and vaccination (Parliamentary question), 978
Alimentary canal, sensibility of, in health and disease. Goulstonian lecture by Dr. A. F. Hertz, 1051, 1119, 1187; (leading article), 1215; sensibility of variations in, 1193
Allbutt, Sir T. C., Soranus of Ephesus, 955
Allchin, Sir W. H., reconstruction of the University of London (leading article), 1363
Allen, Dr. B., of Braintree, forgotten Essex naturalist, 1367
Allen, Mr. H. E., General Medical Council election, 1911, 1228
Allen, Dr. R. W., Vaccine Therapy, its Theory and Practice (review), 449
Allen's Commercial Analysis, 1911 (review), 1431
"Allergie" (Dr. C. von Pirquet) (review), 746
Almond, Dr. G. H. H., cerebral œdema and epileptiform convulsions, 1082
Almsgiving, indiscriminate, 1522
Altrincham Isolation Hospital, new, 335
Ambulance Examination Questions: Catechism on First-aid to Sick and Injured (Dr. D. M. Macdonald) (review), 815
Ambulance transport, 812
America, meat imported from (Parliamentary question), 632; sale of poisons in (Parliamentary question), 1109
American Association for the Conservation of Vision, 1679
American Medical Association, nauguration of prize contest for health problem cartoons, 1464
American Medical Editors' Association, 1680
American Society for the Study of Alcohol and Other Narcotics, 1315
Amido-azotoluol medicinale "agfa," 383
Amiens School of Medicine closed, 410
Amputation, prevention of pain after, by injection of solution of quinine, 457
Amsterdam, cancer mortality in, 1592
Anæmia, Part I., Vol. I., Normal and Pathological Histology of the B'ood, 1910 (Prof. A. Lazarus and Dr. O. Naegeli) (review), 105; ankylostoma, pathology of, 720; fatal case of, sections of the spinal cord and posterior root ganglia from, 1354; von Jaksch's, 1206; pernicious, case of, 1080; treatment of case of, 617; some theories as to cause of, 721; splenic, case of, 1079
Anæsthesia, administration of stimulants under, 331; general, combined with narcotics, notes on 300 cases (Dr. G. Brown), 1005; general, improved apparatus for administering oxygenated and warmed vapours of ether and chloroform for, 304; inquests and deaths during, 46; of palate, pharynx and larynx, and paresis of the palate, 1645; position of present reform movement in, 1672; (Sir F. W. Hewitt), 1486, 1562; in post-pharyngeal abscess, 440; reflex effects from stimulation of nasal mucous membrane during, 440; spinal (stovaine), Cæsarean section under, 304; total, in certain areas accompanying syringo-myelia, case of, 236
Anæsthetic ($C_2E_3$), death under, 1350
Anæsthetic, pantopon as (Mr. C. L. Leipoldt), 368
Anæsthetics, general, discussion on, 743; in intestinal obstruction, value of gastric lavage, 1534, 1669; intravenous injection of, 1386; position of present reform movement in (Sir F. W. Hewitt), 1486, 1562

ANALYTICAL RECORDS FROM THE LANCET LABORATORY.—Albulactin, 34—Amido-azotoluol Medicinale "Agfa," 383—Atherium (White Metal Alloy), 383—Bromural, 1288—Brusson Jeune Bread, 1581—Calogen Block, 34—Cellulose Films, 35—Concentrated Diphtheria Antitoxin, "Wellcome" Brand, 1288—Concentrated Grape Juice, 673—Dietetic Stout, 34—"Flankets," 35—Formarose Tablets, 35—Galvanit, 35—Gaultheria Embrocation, 1288—Groatlings, 35—Iodine Tubes, 1288—Nontox, 1581—Omnopon, 673—Ozet Baths, 673—Pepsin and Bismuth, 1288—Pergenol, 816—Presler Water, 1581—Pyshan Points Tea, 383—(1) Quinine and Urea Hydrochloride Solution; (2) Tuberculin (de Carle Woodcock blister reaction); (3) Parodontal Streptococcus Vaccine; (4) Nargol Bougies; and (5) Corpora Lutea Capsules, 1581—Rusks, 35—Sea-water Plasma, 383—Shaker Salt, 816—Standard Germ Food, 816—Streptococcus Vaccine Rheumatic Fever, 383—Suprarenalin Solution, 383—Thermal Springs of British Columbia, 673—Trilactine Ferments, 383—Validol, 816—"Vaparole" Epinine, 816—(1) Vaparole and (2) Solution Hemisine and Cocaine Hydrochloride; (3) "Tabloid" Photographic Chemicals for Colour Photography, 34

Anaphylaxis and toxæmia of pregnancy, theory of connexion between, 810
Anarchism and the criminal (leading article), 39
Anatomical and mechanical factors in accommodation, 1702; Model (Human Female) (Mr. F. Norman and Dr. W. G. Stone) (review), 173
Anatomists, position of Sir Charles Bell amongst (Dr. A. Keith), 290
Anatomy, Andreas Vesalius, Reformer of (Dr. J. M. Ball (review), 590; Applied (Prof. G. G. Davis) (review), 814; Remarks on (review), 1669; Diagnostic, and Physical Examination, 1910 (Dr. C. B. Slade) (review), 172; history of, Encyclopædia Britannica, 530; Human, for Art Students (Sir A. D. Fripp and Mr. R. Thompson) (review), 105; Pathological Plates (Dr. A. Kast and others), 1910 (review), 669; Practical, Cunningham's Manual of (late Dr. D. J. Cunningham) (review), 309; racial, of Philippine Islanders (Dr. R. B. Bean) (review), 944; Surgical, Manual of, 1910 (Mr. C. R. Whittaker) (review), 30; Veterinary, Text-book of (Prof. S. Sisson) (review), 107
Anatomy and archæology, survey in Nubia, 41
Anatomy Bill, South Africa, 1240
Anatomy of Plants (Mr. W. C. Stevens) (review), 513
Anders, Dr. J. M., Text-book of the Practice of Medicine (review), 668
Anderson, Dr. H. M., administration stimulant during anæsthesia, 331
Anderson, Dr. J. F., and McClintic, Dr. T. the bacteriological standardisation of infectants, 43
Anderson, Dr. K., obituary, 970
Anderson, Dr. S., Hints to Dressers, (review), 1087
Andrew, Dr. C. T., observations on 3000 living rats in North China, 1382
Andrew, Mr. S., "Dr. Grey," 1911 (review), 108
Andrew, late Dr. William, memorial to, at Launceston, 905; obituary, 336
Andrews, Dr., rupture of the large intestine due to compressed air, 524
Aneurysm of groin, 103; of innominate artery, proximal ligature, recovery (Mr. P. Sargent), 1200; saccular, of second part of aorta, 812; springing from region of cœliac axis, treatment by operation with introduction of wire tent, 27, 28
Angina pectoris, rest in bed in, 254; with pulsus alternans, abnormal forms of breathing in cases of (Dr. J. D. Windle), 1260
Angiomata of left loin and leg in girl aged 4½ years, 584
Angio-sarcoma (see Perithelioma)
Aniline-stained microscopical preparations, fading of (Dr. A. C. Coles), 876, 895
Animal Parasitology (Dr. E. R. Stitt) (review), 669
Animals, diffuse lipoma in (Sir J. Hutchinson), 1345; experiments on, attitude of Royal Society for the Prevention of Cruelty to Animals regarding, 1439; experiments on, in reference to development of tuberculosis, 1733; lower, nuchal lipomata in (Sir J. Hutchinson), 800
Animals and man, nuchal lipomata in, 1345
"Annals of Tropical Medicine and Parasitology" (THE LANCET review of), 1380, 1457
Aniridia and lenticonus, congenital, 1208
Ankylostoma, duration of infectivity, 719; eggs of, methods of detecting, in fæces, 783; life-history of, 717; modes of infection, 718; two causative organisms, 719
Ankylostoma anæmia, pathology of, 720
Ankylostoma infection (Dr. A. E. Boycott), 783; conditions favouring infection by skin, 790; conditions which determine prevalence of, 785; diagnosis of, 783; insanitary conditions and spread of, 790; (leading article), 889; Milroy lectures (Dr. A. E. Boycott), 717; treatment and prophylaxis of, 859
Ankylostomiasis in Florida, 1094
Ankylostomiasis, symptoms of infection, 719
Annals of Tropical Medicine and Parasitology (review), 515, 1286, 1380, 1457, 1670; THE LANCET review on, 1533
Annapolis, Naval Academy, outbreak of typhoid fever at, 201
Annato employed as food colouring, 1657; substitute, investigation into composition of, 1600
Annual Charities Register and Digest, 1911 (review), 1648
Annual Post-graduate Review (Jahreskurse für Ärztliche Fortbildung) (review), 516
Anorexia nervosa in Jewess aged 10 years, 584
Antelopes of Uganda, possibilities of their being reservoirs of sleeping sickness virus, 1023
Anthrax and felt, 1148
Anthropoids, growth changes in, compared with those seen in acromegaly, 998
Anthropology of ancient British races (Hunterian lectures) (Dr. A. Keith), 722; New Methods of, and Showing their Application to Filipinos (Dr. R. B. Bean) (review), 944; physical, of the aboriginal Australian and Tasmanian, 1150
Antibodies, 425, 486; applications in diagnosis, 486; total, estimation of, 487
Antigen, standardisation of, 567
Antisepsis and sepsis, rôle of, in medicine (Dr W. Hunter), 79
Antiseptic, iodine as, 179; or aseptic methods, 330
Antiseptics, efficacy of, 1366
Antistaphylococcal defence, mechanism of, recent views as to, 191
Antitoxin (see also Diphtheria antitoxin), 1288; large doses of, in diphtheria, 1614
Antityphoid inoculation in army, 123
Antivaccination in county Wexford, 1105
Antivivisection Bill (New York), 1315
Antivivisection tactics, 342; (see also Church Antivivisection League)
Antivivisectionists in Bristol, 769; humour of, 1623; latest move by, in New York, 846
Antrum of Highmore, gummatous, 1079
Aorta, saccular aneurysm of second part of, 812
Aortic disease, case of, 236; valve, calcareous degeneration of, with two segments, specimen from case, 665

Aphasia, singular case of, 705
Aphonia, functional, case of, in boy aged 15, 1076; recurrent, case of, 440
Apoplexy, suprarenal, case of (Dr. R. Waterhouse), 577
Apothecaries' Hall, Dublin, appointment of assistant examiner in surgery, 1513; of Ireland, pass-lists, 477, 1394
Apothecaries' Hall of Ireland and National Insurance Bill, 1722
Apothecaries' Society of London, appointment of assistant examiner in surgery, 1513
Apparatus, improved, for administering oxygenated and warmed vapours of ether and chloroform for general anæsthesia, 304
Appendicectomy, with special reference to treatment of adhesions, 811
Appendicitis and acute intussusception, two interesting cases of (Mr. L. C. Martin), 1133; and Other Diseases of the Vermiform Appendix (Dr. H. A. Kelly) (review), 744; chronic, 1385; simulating pulmonary tuberculosis, 546; complicated by abscess of liver, 511; enamelled steel wire and, 779; gonorrhœal inflammation of vas differens, simulating, 753; hidden dangers of, plea for early operation (Mr. H. J. Paterson), 1272; necessity of early operation in, illustrated by case of (Dr. D. D. Malpas and Dr. Ph. de Lostalot), 1698; treacherousness of, 229
Appendix, disease of, association of duodenal ulcer with (Mr. H. J. Paterson), 97; inability to diagnose gross lesions of (Mr. E. M. Corner), 1347; intussusception of specimen, 1354; life-history, function, and inflammation of, 239; vermiformis, case of complete intussusception of, 229; strangulated hernia of (Dr. R. Ollerenshaw), 734
Appointments, weekly list of, 71, 135, 205, 280, 347, 411, 480, 555, 633, 711, 777, 854, 914, 979, 1046, 1112, 1181, 1245, 1322, 1397, 1475, 1550, 1622, 1683, 1742
Arany, Dr. S. A., contributions to the physiology and pathology of the assimilation of albumin, 502
Arbroath, epidemic of diphtheria in, 268; Infirmary, proposed, new, 338
Archæology and anatomy, survey in Nubia, 41
Archives of Internal Medicine (review), 516
Arendt, Dr., malignant growths treated by radium, 547
Argentina, Past and Present (Mr. W. H. Koebel) (review), 590
Aristotle, Works of (review), 1012
Arklow, recent outbreak of typhus fever at, 970
Arloing, Prof., obituary, 971
Armand-Delille, M. P. F., Technique du Diagnostic par la Méthode de Déviation du Complément (Technique of Diagnosis by the Method of Deviation of Complement), 1911 (review), 1646
Armit, Mr. H. W., Barlow, Sir T., and Ilkeston, Right Hon. Lord, International Hygiene Exhibition at Dresden: an appeal, 189
Armour, Mr. Donald, operation for spinal cord tumour, 1208
Armstrong, Dr. H., cranial asymmetry due to postural causes, 578
Armstrong, Mr. H. E., discussion on cubicle isolation, 1077
Armstrong, Mr. H. G., discussion on after-history of cases of albuminuria occuring in adolescence, 1136
Armstrong, Mr. W., discussion on climatic and balneological treatment of neurasthenia, 664
Army and navy, Austrian, health of, 1314
Army along the Mexican Border, medical care of, 1177
Army, British, antityphoid inoculation in, 123; health of, in 1909, 316, 532, 607, 690; European, in India, health of, 1300; flogging case in, proving fatal (anecdote of the Founder of THE LANCET), 1324; French, health of, 329; health of, 261; native, of India, health of, 1447; United States, canteen in, 1177
Army hospitals, 631
Army Medical Corps, Manual of, 1321; Germany, inadequate supply of candidates for, 1237
Army Medical Services, recent tendencies in development of, 25
Arsenic, lesser known uses of, 1210
Arsenobenzol (salvarsan) in Hungary, 340
Arsenobenzol (606) in treatment of syphilis, 1704
Arteries, femoral and popliteal, specimen of, from case of senile gangrene, 883; isolated, reaction of, to certain drugs, 939
Arterio-sclerosis in medical practitioners, 972; and relation of, to changes in media of arteries, 1655
Artery, central, of retina in child, embolism of, 375; femoral, thrombosis of, and phthisis in association with recurrent scarlatiniform erythema, 1297; innominate, aneurysm of, proximal ligature, recovery (Mr. Percy Sargent), 1200; media of changes of, and arterio-sclerosis, relation between, 1655
Arthritis, suppurative, of knee-joint, due to influenza bacillus, occurring in baby aged 6 months (Dr. E. T. Fraser), 1573
Arthropathy, rare, 808
Ascites in splenomegaly, 375; treated by lymphangioplasty (Mr. R. A. Stoney and Mr. T. G. Moorhead), 1069
Asclepius, children of, and the goose, 681
Aseptic or antiseptic methods, 330
Ash, Dr. E., care of the nervous, 1028

Asylum Workers' Association, annual general meeting, 1469
Asylum workers, organisation of, 906
Atavism, acromegaly as manifestation of, 993
Atelectasis, therapeutic production of, 1733
Atherium, white metal alloy, 383
Athetosis in a school girl, aged 9 years, 741
Atkins, Maj. C., discussion on ambulance transport, 812
Atlas, Stanford's Indexed, of County of London with Parts of Adjacent Boroughs and Urban Districts (review), 1361
Atropine, discussion on use of, by injection before inhalation anæsthesia, 736
Atrophy, progressive spinal muscular, of infants, 439; secondary optic, due to (? cerebellar tumour), 880
Attfield, Prof. J., F.R.S., obituary, 825
Aundh State (India), new hospital for, 343
Auscultation in life assurance examinations, 1021; of joints (Dr. A. E. Garrod), 213
Austin, Mr. E. C., presentation to, 279

AUSTRALIA, CORRESPONDENCE FROM.—Peculiar poisoning case; Medical inspection of schools; Radium; Early closing for pharmaceutical chemists; Obituary, 344—Compensating dairymen; Australian meat; Contagious dairy disease; Fly peril; Decline of rabbits; Health of Western Australia; Consumption Hospital, 773—Tuberculosis Conference; Melbourne Hospital, charitable bequests; Sydney Hospital; Broken ribs in asylum patients; Health of Tasmania; Personal, 1040—Victorian Board of Health; Friendly Societies' Hospital, 1240—Prahran poisoning case; Tuberculosis Conference; Phenomenal rainfall; Radium, 1241—Federal quarantine; New South Wales Branch of the British Medical Association; Federal appointment; Remarkable case; Medical career; Diphtheria antitoxin dosage; Adelaide Hospital; Personal items, 1614

Australia, phenomenal rainfall in (1911), 1241; pioneer medical work in, 683; Western, health of, 773
Australian meat, 773
Austria, number and distribution of medical practitioners in, 771; reappearance of cholera in, 840, 1735; State Institute for the Care of Mothers and Infants, 64; Watering-places of, Medical Guide to, 1910 (Dr. H. Morré) (review), 173
Austrian Cancer Research Society, 772
Austrian hospital, new, at Constantinopie, 772
Austro-Hungary, cholera in, 395
Author, medical, responsibility of, 1237
Auto-inoculation, rôle of, in medicine (Dr. C. Riviere), 220; and massage in case of gonorrhœal synovitis (Mr. J. R. R. Trist), 374
Auto-intoxications, Guelpa treatment of, 1033
Automobiles, smoking, 274
Autoserotherapy, 1527
Autunite (hydrated uranium-calcium phosphate), 766
Avery, Dr. J. S., quinine and blackwater fever, 1591
Aviation and attendant risks of, 1613
Ayoux, M., hæmoglobinuric bilious fever in the Island of Réunion, 702

## B

Babcock, Dr. J. W. (see Marie, Dr. A., Pellagra, authorised translation from the French)
Babies' club, new, in Dublin, 970
Baby, aged six months, case of suppurative arthritis of knee-joint, due to influenza bacillus, occurring in (Dr. E. T. Fraser), 1573; suffering from tuberculous meningitis, 941
Baccelli, Prof. G., treatment of tetanus by subcutaneous injections of phenol, 1714
Bacilli of Gaertner group in causation of subacute and chronic forms of epidemic diarrhœa in children, 1207
Bacillus, virulence of, 1458; aerogenes capsulatus, infection by, cases of, 445; (see Influenza bacillus); isolated during plague epidemic characters of strain of, 1310; of Long Life (Mr. L. M. Douglas) (review), 1285; typhosus atypical, house epidemic of enteric fever due to carrier of (Dr. W. J. Wilson and Dr. J. A. Sinton), 1002; viability and possible variation of, 1148
Bacillus pyocyaneus, vitality of, 1455
Back, tumour of, 1206
Bacteria, intestinal, variability in gas-forming power of, 235; Their Relations to Health and Disease (Dr. T. M. Prudden) (review), 945
Bacterial Therapeutics and Prophylaxis, Bacterial Diagnostic Agents, 1910 (Prof. R. T. Hewlett) (review), 1357
Bacteriological research laboratory for South Arica, 1546
Bacteriological standardisation of disinfectants, 43
Bacteriological work in India, 1447
Bacteriologist (city) for Dublin, 1390
Bacteriology, Agricultural, Theoretical and Practical (Mr. J. Percival) (review), 1085; Aid to (Mr. C. G. Moore and Mr. W. Partridge), (review), 1085; of chronic post-nasal catarrh, 302; General, Text-book of, 1910 (Profs. W. D. Frost and E. F. M. Campbell) (review), 169; Text-book of (Dr. E. O. Jordan) (review), 450; and general parasitology, review of (supplement to "Medical Officer"), 255; Manual of (Dr. R. Muir and Dr. J. Ritchie) (review), 670; Practical (Dr. E. R. Stitt) (review), 669; public exhibition of, in United States, 66; Text-book of (Prof. P. H. Hiss and Prof. H. Zinsser) (review), 1358
Bacup and shuttle-kissing committee, 1387
Badgerow, Mr. G. W., case of lingual thyroid, 440; and Powell Dr. H. W. F., case of Vincent's angina, 1076
Baemeister, Dr., experiments on animals in reference to the development of tuberculosis, 1733
Bagdad, English Mission Hospital at, 1247

Coupland, Mr. J. A., ulcer exposing the inner end of the right clavicle, 587; and Teale, Mr. M. A., Hunterian chancre of the left lower eyelid, 1079
Coventry, isolation hospital at, 34
Coventry school clinic, 1369
Cow, Dr. D. V., reaction of isolated arteries to certain drugs, 939
Cows, tuberculosis in (Parliamentary question), 1109
Cox, late Mr. H. W., tablet to, 910
Cradle of the Deep, an Account of a Voyage to the West Indies (Sir F. Treves, Bart.) (review), 1084
Craig, Dr. W., complimentary dinner to, 474
Craigmile, Dr. A., presentations to, 1676
Crandon, Dr. L. R. G., Surgical After-treatment: Manual of the Conduct of Surgical Convalescence (review), 311
Cranial asymmetry due to postural causes (Dr. H. Armstrong), 578
Cranio-cleido-dysostosis, hereditary, and Mendelism, 124
Crawford, Mr. D., and Alexander, Dr. D. M., specimens of primary and secondary tubercle of tongue, 445
Crawford condenser, 1088
Crediton, Devon, sewerage of, 1109
Crepitation, reversible, pulmonary, in cardiac failure (Dr. A. Morison), 1202
Crequy, M., question of depopulation in France, 198
Crespigny, Mrs. P. C. de, Valley of Aohor (review), 592
Cretin, treated with thyroid extract, 941
Cretinism, case of, 1426
Crichton, Dr. H., improved forceps, 246
Crichton-Browne, Sir J., mental nursing, 1028
Crime, increase of (leading article), 519; suppression of news of, in newspapers of Illinois, U.S.A., 1736
Criminal statistics and penal reform, 683
Criminals, juvenile, treatment of, 338; and anarchism (leading article), 39; sterilisation of, in United States, 1464
Cripps, Mr. W. Harrison, discussion on cancer of rectum, 101
Critchett, Sir A., discussion on conical cornea, 1701, 1702
Crofton, Dr. W. M., discussion on case of athetosis, 741; on a diseased placenta, 742; on malignant ovaries, 1079; on treatment of eclampsia, 306; etiology and treatment of diabetes mellitus, 1009
Cromer, Earl, and others, Research Defence Society, 263
Crookshank, Dr. F. G., presentation to, 911; "whole time" medical officer of health, 57
Cross, Mr. F. R., discussion on pituitary body and lesions of optic chiasma, 303
Cross, Dr. J., infectivity of whooping-cough, 1623
Cross, Mr. K. Stuart, the physical anthropology of the aboriginal Australian and Tasmanian, 1150
Cross, Miss V., Self and the Other (review), 515
Crossen, Prof. H. S., Diagnosis and Treatment of Diseases of Women, second edition, 1910 (review), 171
Crossley Sanatorium, addition to, 1733
Crowe, Dr. H. W., an experimental investigation into the question of the possibility of modifying the effect of an inoculation of tuberculin by combining it with a local anæsthetic, 368
Crownhill Convalescent Home, Plymouth, annual meeting, 1241
Cruickshank, Dr. L. D., appointment of, 906
Crystal Palace, preservation of surroundings as open space advocated, 1048
Crystals, 1092
Cubicle isolation; its value and limitations, 1077
Culture tests for plague bacillus, 1173
Cunningham, Dr. D. J., the late, Cunningham's Manual of Practical Anatomy, 1910 (review), 309
Cunningham, Capt. J., destruction of fleas by exposure to the sun, 1022
Cunningham, Col. J. A., death of, 261
Curette and knife, combined for removal of tarsal cysts (Mr. A. A. Bradburne), 174
Currie, Dr. J. R., appointed medical officer of health for Fifeshire, 1389
Currie, Dr. D. W., and Bramwell, Dr. E., acute anterior poliomyelitis, 442
Curzon, Lord, installation of, as Lord Rector of Glasgow University, 337
Curzon-Howe, Admiral Sir A., death of, 696
Cushing, Dr. H., ocular, paralysis in intracranial tumour, 45
Cushny, Dr. A. R., Text-book of Pharmacology and Therapeutics, or the Action of Drugs in Health and Disease, 1910 (review), 1426
Cut-throat, attempt at suicide by, followed by large fistulous opening just above hyoid bone, case shown, 166; power of speech in (Mr. D. H. Mehta), 228
Cyst, pancreatic, formation of, following acute pancreatitis, 1280; of upper extremity of the femur, case of, 665
Cystic disease of kidneys, case of, 1423
Cysticercus of brain, 407; cellulosæ, specimen, 884
Cystocele, buttress operation for, 1209
Cystoscopy, Manual of (Dr. J. B. Squier) (review), 1284
Cystotomy, suprapubic, improved drainage-tube for, 1016; transperitoneal, for tumour of bladder (Mr. S. Pringle), 214; (G. G. Turner), 470

## D

Dairy disease, contagious, in Australia, 773
Dairy inspection and Local Government Board (Ireland), 61
Dairymen, compensating, in Australia, 773
Dalby, Mr. A. W., presentation to, 478
Daley, Mr. W., tragic death of, obituary, 1460
Daley, Dr. W. A., appointed medical officer of health of Bootle, 1676
Dalmady, Dr., on the misuse of hydrotherapeutic measures, 1239
Dalton, Mr. C., remedy for cancer in 1484, 1113
Dando, Mr. E. A., presentation to, of Edward medal, 630
Dante, scientific knowledge of, 1218
Darier's disease, case of, 881
Darracq two-seater 10-h.p. four-cylinder, 526
Dartford, meeting to consider National Insurance Bill, 1543
Dartmouth College, sickness at (Parliamentary question), 1046
Darwin, Influence of, in Sciences of Humanities (Dr. J. M. Baldwin) (review), 591
Davidson, Dr. J., diet and inoperable cancer, 902
Davidson, Dr. S., case of Landry's paralysis occurring during pregnancy and the puerperium, 166
Davies, Dr. D. S., report on tuberculosis in Bristol, 195
Davies, Mr. F. C., case of thrombosis of the superior vena cava and great veins, 1345
Davies, Mr. H. R., reduction of infantile intussusception by air enema, 1454
Davies, Mr. J. E., rebates on petrol tax for medical men, 264
Davis, Prof. G. G., Applied Anatomy, 1910 (review), 814, 1669
Davis, Dr. H. J., case of acute vertigo, 585
Daw, Mr. S. W., and Dobson, Mr. J. F., extensive disease of the glands of the neck treated with Coley's fluid, 1078
Dawkin, Mr. G. M., improved splint for Colles's fracture, 674
Dawson, Sir Bertrand, the microbic factor in gastro-intestinal disease and its treatment, 1124
Dawson, Dr. W. R., appointment of, 845; discussion on tumours of brain, 167; appointed inspector of lunatics, Ireland, 970; presentation to, 1242
Day, Dr. J. M., discussion on rheumatism in childhood and in adult life, 741
Dead, burial of, during plague in China, 706
Deaf, education of, its present state in England, with suggestions as to its future modifications and development (Mr. M. Yearsley), 495, 574, 652; (leading article), 678
Deaf-mutism, application of eugenics to, 652
Deafness, case of, arising from epidemic parotitis, 436; experience of, 330; method of determining existence of, 1305; some common forms of (Dr. W. H. Kelson), 1007; (see also Gun deafness)
Dean, Dr. H. R., complement fixation method in differentiation of various members of typhoid and paratyphoid group, 235
Dearden, Mr. W. F., certificates of fitness by certifying surgeons, 1734; relation of public health to industrial diseases, 164
Death, sudden, following prophylactic injection of diphtheria antitoxin, 1654
Death-rate, "corrected," 338; from cancer, statistical study, 525; high, in county borough of Middlesbrough, causes of, 51; in India (Parliamentary question), 1473; low, at Stalybridge, 620; of New York, decrease of, 1679
Death registration, retrograde step in (Registrars-General weekly returns criticised), 189
Deaths and inquests during anæsthesia, 46; natural increase of population by excess of births over, in London, 322
Debts, Collection of, Simplified, or County Court Practice made Easy (review), 1086
December, 1910, weather of, 115
Deformity of female generative organs, two uncommon forms of, one causing symptoms simulating intestinal obstruction (Dr. J. A. C. Macewen), 798
Degeneracy and consanguinity, 1255
Degenerates, treatment of (Parliamentary question), 1244
Delépine, Prof. S., bovine tuberculosis, 278
Delirium, acute, in association with attack of epidemic parotitis followed by case of acute orchitis occurring in undescended testis, 23
Delivery, natural, after Cæsarean section, case of, 1079
Delusions in melancholia, 867; pathogenesis of, 1355
Dementia præcox, 1426
Dempsey, Dr. J. P., discussion on case of sarcoma of larynx, 1704; dicussion on treatment of laryngeal stricture, 238; and Blayney, Mr. A. J. M., arseno-benzol ("606") in the treatment of syphilis, 1704
Denier, M., and Bréaudat, M., preventive and curative treatment of beri-beri, 63
Dental instruments made of tantalum, 1247
Dental naval officers of United States, 274
Dental operations, prolonged, new method of administering nitrous oxide for, with or without oxygen (Mr. N. S. H. Warner), 371
Dental practice, unqualified, 207
Dental profession for women, 1388
Dental surgery, petition of Paris students, 475; use of cocaine in, followed by grave and prolonged cardiac failure (Dr. F. W. Price and Dr. A. B. Leakey), 797
Dental Surgery and Pathology (Mr. J. F. Colyer) (review), 242
Dentistry, curriculum in, 320
Dentists and rebates on motor spirit duty (Parliamentary question), 852
Dentists Register for 1911 (review), 1285
Denture (see Teeth, artificial)
Depopulation of France, agency of midwives in, 198
Derby, county borough of, annual report of medical officer of health, 120
Dermatitis, extensive gummatous, case of, treated by intramuscular injection of salvarsan, 1078; from teak, 895, 903
Dermatological Literature, Epitomised Index to (Mr. A. W. Williams) (review), 380
Dermatology, evolution of 1555; Introduction to (Dr. N. Walker) (review), 1360; progress of, since Hunter's time (Dr. J. H. Sequeira), 1555; Seventh International Congress of, 1395
Dermo-fibromatosis, familial pigmentary, three cases, 162
Dermoid, ovarian, specimen, 239
Descomps, Pierre, Travail de l'Amphithéâtre d'Anatomie des Hôpitaux: Recherches d'Anatomie Chirurgicale sur les Artères de l'Abdomen (review), 449

Deric, E., and Gardère, C., recurrent scarlatiniform erythema associated with phthisis and thrombosis of the femoral artery, 1297
Devine, Dr. H., the pathogenesis of a delusion, 1356
Devon and Cornwall Ear and Throat Hospital, Plymouth, 499; sanatorium for consumptives, Didworthy, 61, 1223
Devon County Infirmary, 845
Devon county memorial to late King, 631
Devon, East, proposed medical officer of health for, 1233
Devonshire, medical inspection of school children in, 518; superstitions of, 281
Dewar, Dr. T. W., discussion on duodenal ulcer, 740; treatment of phthisis by intravenous injection of solution of iodoform, 377
Diabetes mellitus, cure for, 281; etiology and treatment, 1009; and gout, influence of, upon tuberculous infections, 805; Guelpa treatment of, 1033; influence of, on tuberculous infections, 825; oatmeal, treatment in, 1733; potatoes in dietary of patients suffering from, 702; statistics of, in Paris, 971; treatment of, 1456; taka-diastase in treatment of, 826; (see also Coma, diabetic)
Diagnosis, application of antibodies in, 486; by physiognomy, 704; case for, swelling on right side of chest, 307; immunity reaction in (leading article), 594; especially of tuberculosis and syphilis (Dr. W. D'Este Emery), 485, 564
Diagnosis, Medical (Dr. W. M. Stevens) (review), 1084
Diagnosis, Technique of, by Method of Deviation of Complement (Technique du Diagnostic par la Methode de Déviation du Complément), 1911 (M. P. F. Armand-Delille) (review), 1646
Diaries and calendars of New Year, 1911, 33
Diarrhœa, deaths from, in New York, 1315; epidemic, sub-acute and chronic forms in children due to bacilli of Gaertner group, 1207; infantile (Dr. W. Tibbles), 580
Diastolic sound and impulse, cardiac, note on (Dr. T. Fisher), 11
Diatheses, modern views on, 1732
Diazo reaction, Ehrlich's, 126
Dick, Dr. J. S., series of cases with tuberculous affections undergoing treatment, under opsonic control, with tuberculin (T.R.) inoculations, 1080
Dictionaries, Medical (review), 448
Didsbury memorial to Dr. J. M. Rhodes, 476
Diet, effect of, upon inoperable cancer, 1033; influence of, on pressor bases of urine, 1409; and inoperable cancer, 127, 902, 967
Diet and Maximum Duration of Life (Dr. C. Reinhardt) (review), 311
Dietary of diabetic patients, potatoes in, 702
Dietetics, Principles of (Dr. R. Hutchison) (review), 1505
Dietetics and Nutrition, 1910 (Prof. W. S. Hall) (review), 171
Dieulafoy, Prof. G., Text-book of Medicine, 1910 (review), 667
Dieupart, Dr. L., and Bernheim, Dr. S., treatment of tuberculosis by radio-active menthol iodine, 1525
Digestion, influence of tobacco upon, 264; influence of spleen on, 1610
Digestive Apparatus, Diseases of (Dr. H. Huchard) (review), 1427
Digestion, artificial, notes on, 1659
Digestion, behaviour of dyes during, 1639
Dighton, Mr. C. A. A., self-retaining mastoid retractor, 817
Digitalis, heart-block following administration of, case (Dr. E. B. Laslett), 19
Dilatation, congenital, of colon in girl aged 6 years, 583
Dinners, various, annual dinner of McGill medical students, 626; Association of the Irish Medical Schools and Medical Graduates, 1611; Brussels Medical Graduates' Association, 1681; to Sir H. Butlin, 1294, 1673; to coachmen and chauffeurs of medical men, 281; complimentary dinner to Sir David C. McVail, 269; Coroners' Society of England and Wales, 1656; Dublin University Biological Association, 701; Durham Medical Graduates' Association, 1740; Edinburgh Indian Medical Service dinner, 545; Edinburgh University Club, 628; Fishmongers' Company, 911; Glasgow R.A.M.C. officers' dinner, 623; Glasgow University Club, 1546; Indian Medical Service, 1738; Irish Medical Schools and Graduates' Association, 850; ladies' dinner in aid of King's College Hospital Removal Fund, 1276; Liverpool School of Tropical Medicine, 267; London School of Clinical Medicine, 910; medical students, University of Liverpool, 60; Medico-Psychological Association of Great Britain and Ireland, 693; Metropolitan Police Surgeons' Association, 629; New South Wales Branch of British Medical Association, 1614; past and present students' dinner, Durham University College of Medicine, 544; Royal Institute of Architects, 624; Royal London Ophthalmic Hospital, 71; Royal Sanitary Institute, 1471; to Dr. Stephen Smith, 704; Society of Tropical Medicine, 1739; South African Civil Surgeons, 1242, 1620; University of Bristol Colston Society, 196; West London Medico-Chirurgical Society, 553
Dioxy-diamido-arseno-benzol ("606"), treatment of syphilis by (Mr. C. F. Marshall), 501
Diphtheria, circumvention of prevalence of, 1586; contagion of, due to cats, 545; epidemic of, in Arbroath, 268; gangrene of limb during convalescence from (Dr. A. S. Ransome and Mr. E. M. Corner), 94; outbreak of (Parliamentary question), 913; serum rash and serum sickness in, treatment by administration of thyroid gland substance (Dr. A. E. Hodgson), 373
Diphtheria antitoxin, concentrated, "Wellcome brand," 1288; gratuitous provision of, in Scotland, 1721; supply of (Parliamentary question), 852; dosage, 1614; prophylactic injection of, followed by sudden death, 1654
Diphtheria bacillus, nutrient media for naked-eye, recognition of, 809
Diphtheria carriers, quarantine for, 753; record of 90 (Dr. A. G. Macdonald), 795
Diphtheria at Johns Hopkins Hospital, 972; in Baltimore, 847; in Dundalk, 62; in Rathfriland, 624, 906; of vulva in child, 600
Diplegia, cerebral athetotic, in girl aged 22 years, 583
Diplomas, medical, granted during Academical year in Paris 1909-10, 132; question of disciplinary cancelling of, 1106
Directories (see "Medicus," Guide Annuaire des Étudiants et des Practiciens)
Dirt and disease among savages, 136
Discipline and Duty, Essays on, Series of Papers on the Training of Children in Relation to Social and National Welfare (review), 1910, 671
Disclaimers, 58, 839, 1113

Explosives, poisonous fumes produced by, 1588
Extremity, left lower, and trunk, hemiatrophy of, accompanying sclerodermia, case of, 236; right upper, infantile paralysis of, 941
Eye, anterior chamber of, sarcoma-like growth in, with 16 years' history, 807; significance of pus in (Mr. J. H. Parsons), 1690; diseases of, treatment (Dr. C. Adams) (review), 1706; by Ehrlich's new remedy, "606," 198; frontal sinus and cerebrum, wound of, caused by pellet from air-gun, 26; left microphthalmic and coloboma of iris in right eye, 208; Microscopical Methods of Examining (Die Mikroscopischen Untersuchungsmethoden des Auges) (Dr. S. Seligmann) (review), 32; right, coloboma of iris in, and left microphthalmic eye, 808; proptosis of, 940; sightless, loss of (Bell v. Hunt), 830; diagnosis chart, 413; Dispensary, Bristol, 1103; Ear, and Throat Infirmary of Edinburgh, 337; in Healthy Conditions, Biomechanical Structure of, Relationship of, to Intra-ocular Fluid (Dr. J. Kuschel) (review), 1085; Hospital, Bristol, report, 471; of patient, piece of steel from instrument in, skiagram of, 666
Eye of surgical needles, new form (Mr. J. Lynn Thomas), 935
Eyelid, left lower, Hunterian chancre of, 1079
Eyesight, defective, of Samuel Pepys, 1687; tests in Mercantile Marine, 1044
Eyestrain, 103; in relation to general health, 541, 698, 767, 839; (Dr. J. Hinshelwood), 429; in Royal Navy, 1355
Eyre, Dr. J. W. H., discussion on surgical treatment of colitis, 1010
Eysell, Dr. A., birth of a mosquito, 1653

## F

Fabricannte, Dr., operative treatment of ureteral calculus, 1220
Face of acromegalics, changes taking place in, 998
Facial nerve (see Nerve, facial)
Factory and Workshop Act, 1907, in relation to Poor-law establishments, 45
Fæcal contamination, influence of, in ankylostoma infection, 788
Fæces, method of detecting eggs of ankylostoma in, 783
Fagge, Mr. C. H., discussion on cancer of rectum, 232; inguinal method of radical cure for femoral hernia, 804
Faisans, M., chronic appendicitis simulating pulmonary tuberculosis, 546
Fallacy about coffee, 458
Fallopian tube, case of chorio-epithelioma of, 883; tuberculous, localised adenomyoma in, removal, 27; and left broad ligament, torsion of, in child (Dr. M. A. Cassidy and Mr. L. E. C. Norbury), 98
Fallopian tube, Purulent Inflammations of, Histological Researches (Die eitrigen Entzündungen des Eileiters: Histologische Untersuchungen (Dr. H. Schridde) (review), 1506
Falmouth, mortuary accommodation at, 623
Falmouth Hospital, foundation stone laid, 1242; foundation stone of new operating theatre laid, 1242
Families, limitation of, in Hungary, opinion of Superior Hygienic Committee, 548
Fano, Prof. G., elected to Italian Senate, 1736
Farbstein, Mr. J. H. (obituary), 975
Far East, plague in, 59
Far Eastern Association of Tropical Medicine, Congress of, 1460; date and place of meeting, 1465
Farm colony for vagrants, 1679
Farquhar, Dr. J., charge of perjury against, 1610
Fat embolism, cerebral, occurrence of, in victims of recent railway accident (Mr. R. J. Godlee and Mr. G. E. O. Williams), 1062
Fat, rôle of, in etiology and progress of cancer (Sir G. T. Beatson), 1560
Favell, Mr. R., impacted uterine calculus simulating uterine fibroid, 27
Favus, eruption of, on abdominal wall of female child, 103
Fawcett, Dr. E., Patrick Cotter, the Bristol giant, 1324
Fawcett, Dr. J., case of cystic disease of the kidneys, 1423
Fayrer, Lieut.-Col. Sir J., appointment of, as superintendent of Royal Infirmary, Edinburgh, 1036
Fearn, Maj. G., bequest of, 1620
February, 1911, weather of, 680
Federal appointment, 1614
Federal Government of United States, action of, concerning rotten egg traffic, 273
Federal Quarantine Department, procedure of, 1614

Fedoroff, von, Prof., intravenous injection of anæsthetics, 1386
Fee, medical, prompt payment ordered in court, 336
Feeble-minded, birth-rate of (Parliamentary question), 1474; care of, 1663, 1734; care of, in Somerset, 472, 622; care and control of (Parliamentary question), 1181; control of, 377; A Guide to Study and Practice (Dr. E. B. Sherlock) (review), 1138; women, illegitimacy among (Parliamentary question), 1244
Feeblemindedness, heredity in relation to, 1251; in Children of School Age (Dr. C. P. Lapage) (review), 1083
Feeding and Care of Baby (review), 450
Feeding of infants, 556; and infant birth, problems of (leading article), 1145; history of, from Elizabethan times, 880; by rectum, value of, 939
Feeling and emotion, 353; and will, connexion between, 355
Fees, medical, action for, 338; and National Insurance Scheme, 1306; of medical officers in India, 682
Feet and hands cloven, 24
Fellowship of Royal College of Physicians of London, 957
Felt and anthrax, 1148
Female, Human, Anatomical Model of (Mr. F. Norman and Dr. W. G. Stone) (review), 173
Femur, congenital deformity, 1424; malformation of, 1206; necrosis of shaft of, and acute septic periostitis, case showing repair after, 307; syphilitic osteitis of, 880; third trochanter of ossific centre for, 882; upper extremity of, case of cyst of, 665
Fenwick, Dr. W. Soltau, Dyspepsia, its Varieties and Treatment, 1910 (review), 446
Fergusson, Rev. R. M., The Vagrant, What to Do with Him, 1911 (review), 1087
Ferrier, Sir D., complimentary dinner to, 775
Fertility, 349; (leading article), 315; relation of, to social condition, 323
Fever, Relapsing, Experimental Chemotherapy of (Professor P. Ehrlich, Dr. S. Hata, and others) (review), 1427
Fever hospitals of Metropolitan Asylums Board, nursing in, 598
Fever Nursing (Dr. J. C. Wilson) (review), 1013
Fevers of Hot Countries and Parapaludism (Parapaludisme et Fièvres des Pays Chauds) (M. P. Gouzien and others) (review), 1011; of West Africa, and Yellow Fever (Mr. E. F. Grune) (review), 515
Fibroid of broad ligament, 507
Fibroid, ovarian abscess simulating, 510; tumour of uterus simulated by impacted ureteric calculus, 27
Fibroid, solitary, of uterus, large circumscribed fibroma of left ovary, and enlarged fibromatous uterus removed from one woman, 1209
Fibroids, red degeneration of, in pregnancy case, 304
Fibrolysin, 90 injections of, and massage in treatment of, case of advanced rheumatoid arthritis, 1078
Fibroma of left ovary, case of, 586; of left ovary, fibromatous uterus, and small fibroid of uterus removed from one woman, 1209; of left vocal cord, case of, 883
Fibromatosis, "nodular," an everyday affection (Dr. W. H. M. Telling), 154; identity with so-called chronic muscular rheumatism (Dr. W. H. M. Telling), 154 (also see Dermofibromatosis)
Fibromyoma of uterus, subtotal hysterectomy for, 40 additional histories (Mr. A. H. G. Doran), 86
Fibromyositis, nodular, 329; case of (Capt. R. Knowles), 734
Fibrosis, chronic, subcutaneous, 376
Fibula, transplantation of, 845
Fick, Prof. R., Handbuch der Anatomie und Mechanik der Gelenke, Vols. II. and III., 1911 (review), 1282
Fiessinger, M., rest in bed in angina pectoris, 254

Grace, Mr. E. M., obituary, 1436
Graham, Mr. C., chronic ulcer of nasal septum, 235
Graham, Mr. C. I., and Rose, Mr. F. A., cases of tuberculous tonsillitis, 440
Graham, Dr. J. A., treatment of scarlet fever by "Milne's method," 1671
Grant, Dr. D., continuous inhalation in pulmonary tuberculosis, 262
Grant Medical College and Indian Medical Service, 1724
Granuloma of retina, peculiar form of, 807
Grape juice, concentrated, 673
Grape sugar, intravenous injection of, 199
Grasset, Dr. J., the marvels beyond science (occult phenomena), 318
Graves's disease, 1308 case of, 304, 735; histological research in, 1308; in a boy, 1423; two cases, 586
Gray, Mr. E., medical inspection of school children, 761
Gray, Dr. G. Douglas, a report on the septicæmic and pneumonic plague outbreak in Manchuria and North China, 1152; diffusion of plague epidemic throughout the affected areas in relation to time and place and the influence on its dissemination of roads, rivers, railways, and shipping, 1310; origin of plague infection, 1459
Gray, Mr. J. P. W., discussion on syphilitic skin and throat affections, 509
Gray, Dr. Sarah, dysmenorrhœa, 884
Gray's Hospital, Elgin gift to, 1037
Great Britain, health resorts for foreign invalids in (Dr. N. Wood), 12; representation at International Hygiene Exhibition at Dresden, 182
Greathead, Dr. J. (obituary), 67
Great Ormond Street Hospital, attack on by *John Bull*, 774
Greece, mediæval attitude in, 956
Greek Hospital, Constantinople, pathological ward for, 1175
Greek, medical lexicographer on, 1737
Greek play at Bradfield College, 1477
Green, Mr. A. S., discussion on oral sepsis, 1081
Green, Dr. C. D., National Insurance Bill, 1666
Greenwood, Mr. C. H., case of red degeneration of fibroids in pregnancy, 304
Greenwood, Dr. M., National Insurance Bill, 1604, 1666, 1726
Grenfell, Dr. W. T., work in Labrador, 412
Gribbon, Lieut. M. C., genius and insanity, 1608
Griffith, Dr. A. H., three cases of optic nerve tumour, 806
Griffith, Dr. T. W., case of Raynaud's disease, 1078; use of the clinical polygraph in cases of actual and apparent pulsation of the liver, 586
Grimsdale, Dr. T. B., case of persistent metrorrhagia, 510
Groatlings, 35
Groin, aneurysm of, 103
Grossmann, Dr. K. A., leprosy in patient showing the macular type, 666
Ground, Dr. E., fatal case of myasthenia gravis, 229
Groves, Mr. E. W. H., case of spontaneous fracture of the leg bones, of doubtful nature, possibly one of mycotic infection, 1416
Grünbaum, Dr. A. S. F., and Grünbaum, Dr. H. G., human pituitary gland, 809; inhibition of growth of inoculable tumours in rats, 809; some experiments of the inhibition of tumour growths in rats and mice, with a suggestion for an empirical treatment in man, 879, 894
Grünbaum, Dr. O., technique of intravenous injection of Ehrlich-Hata preparation "606," 21
Grund, Dr., oatmeal treatment in diabetes, 1733
Grune, Mr. E. F., West African Hygiene, with Recent Observations on Yellow Fever and West African Fevers (review), 515
Guelpa treatment of diabetes, gout, rheumatism, and other auto-intoxications, importance of, from insurance point of view, 1033
Guiana, British, health matters in, 635
Guinea-pigs, lack of, at Pasteur Institute, 1735
Guild of Play, 976
Guilleminot, Dr. H., Radiometrie Fluoroscopique, 1910 (review), 312
Gulland, Dr. G. Lovell, discussion on duodenal ulcer, 741
Gummatous mesaortitis and its occurrence in parasyphilitic disease, 1372
Gun deafness in the navy (Parliamentary question), 1111; in navy (Parliamentary question), 1242
Gunn, Mr. K. E. L. G., discussion on tumours of brain, 167; discussion on acute unilateral pyelonephritis, 1281
Gunshot Wounds, Manual on Military Surgery (Prof. J. L. Reverdin) (review), 1579
Guthrie, Dr. L., Charles Bell and the motor and sensory functions of the spinal nerves, 697, 1032; two cases of muscular atrophy of the peroneal type in father and son, 736
Gynæcological conditions coincident with mental disturbances, 694
Gynecology, Diagnosis in (Dr. W. L. Burrage) (review), 106
Gynæcology, Manual of, 1911 (Dr. T. W. Eden) (review), 1210; Principles of (Dr. W. B. Bell) (review), 744; suprapubic transverse fascial incision in (Dr. T. Wilson), 1198; Therapeutics of (Dr. S. J. Aarons) (review), 588

## H

Haas, Dr. P., Laboratory Notes on Organic Chemistry for Medical Students, 1910 (review), 887
Hæmatemesis, occasional, with indigestion, 1282
Hæmatocolpos, fluid in, nature of, and character of obstructing membrane (Dr. W. B. Bell), 1269; nature of fluid contained in, 805
Hæmatogenous infection, unilateral, of kidney, rare type of, 824
Hæmatological Chart (Mr. G. R. Ward) (review), 1013
Hæmodynamics, knowledge of, 100 years ago, 1484
Hæmoglobinuric bilious fever in Island of Réunion, 702
Hæmolytic jaundice with hæmoglobinuric crises, 458
Hæmorrhage from bowel, 812; of brain in girl aged 13, 1080; from tonsil, 168; uterine, six cases of "utriculoplasty" for, one of which was followed by pregnancy and labour (Dr. V. Bonney), 1266
Hagemann, Dr., intravenous injection of anæsthetics, 1386
Hagger, Mr. H. J., vestry clerk of Liverpool, death of, 195
Haig, Dr. A., diet and inoperable cancer, 127, 1033
Haig, Dr. H. A., new form of chest-piece for the binaural stethoscope, 1088
Halahan, Dr. R. E., note illustrating the treacherousness of appendicitis, 229
Halford, Mr. J., notification of measles, 471
Halifax, county borough of, annual report of medical officer of health, 121
Hall, Dr. A. J., combined posterior and lateral sclerosis, ataxic paraplegia, in man aged 23 years, 587
Hall, Dr. D. G., malignant growth at back of tongue, 168; and Galt, Dr. H., clinical and bacteriological notes on a series of cases of enteric fever admitted to the Sussex County Hospital, 168

Syphilide, pigmentary, in patient with heart disease, case of, notes on (Dr. C. W. Chapman), 1137; ulcerating gummatous, treatment by "606," 1208
Syphilis, 1558; chyliform ascites, dropsy and albuminuria, case of, 439; congenital, treated by "606," 1206; congenital, of heart, 893; Experimental, Chemiotherapy of (Prof. P. Ehrlich and Dr. S. Hata and others) (review), 1427; influence of, upon tuberculous infections, 806, 825; inherited, splenomegaly of, 375; and blue sclerotics in infant, 880; intensive treatment of, 1314; malignant, case of, 936; and mental deficiency, 1206; nasal, primary, sore in vestibule, 441; question of abortive treatment of, 270; secondary, hæmolytic jaundice in, 391; and "606," 837; and "606," reply to Mr. C. F. Marshall's views (Dr. J. McIntosh and Dr. P. Fields), 724; System of, vol. vi., 1910 (review), 104; vol. v., 1910 (review), 512; tertiary, case of, 812; treatment of, by Ehrlich-Hata remedy ("606")) salvarsan, dioxy-diamido-arseno-benzol, 29, 1704; (Mr. C. F. Marshall), 501; (Dr. J. Bresler) (review), 32; (Maj. T. W. Gibbard and Capt. L. W. Harrison), 726; (Dr. G. Stopford-Taylor and Dr. R. W. Mackenna), 26, 1412; (Mr. A. Fleming and Dr. L. Colebrook), 1631; compared with mercury (Maj. H. C. French), 1691; subcutaneous injection, 507; intravenous method (Mr. T. W. Bayly), 153; with salvarsan ("606") by intravenous method (Mr. H. W. Bayly), 153
Syphilitic of thirty years' standing, nerve-deafness in (Mr. A. H. Cheatle), 161
Syphilitic osteitis of infants, 772
Syphilitic ulceration of head and face healed by Erhlich-Hata's "606," 25
Syphon, Puris, 1361
Syringe, improved, 1015; and cannula, three-way, 816
Syringobulbia, case of, with implication of the nose, pharynx, and larynx, 1644
Syringomyelia with total anæsthesia in certain areas, case of, 236
Szendeffy, Dr. de, and others, treatment of tuberculosis by iode menthol radio-actif, 1729

## T

Tabes treated by salvarsan, 666
Tabes and pruritus, relation between, 1670
Tabora, Prof. von, discussion on abnormal peristaltic movements of the stomach, 1609
Tachycardia, paroxysmal, 1425
Tailoring, high-class, in low-class tenements, 1588
Taka-diastase in treatment of diabetes mellitus, 826
Talent, Dr. J. W., annual report on Ashton-under-Lyne school children's health, 478
Talipes valgus of tuberculous origin, painful double, 752
Tampons, solid glycerine-gelatin, 1457
Tantalum, dental and surgical instruments made of, 1247
Tarabagan, fleas infesting, 1383
Tarabagan disease, 1153
Targett, Mr. J. H., microscopical examination in case of hydatid of the uterus, 1700
Tariff, Prussian official, for medical attendance (national insurance scheme) (Mr. G. P. Forrester), 1299
Tarnowska, Countess, mental condition of, 200
Tarring of roads, complaint against (twentieth century hygiene), 1247
Tarsal cyst knife and curette, combined (Mr. A. A. Bradburne), 174
Tasmania, health of, 1040; public health in, 1476
Taunton, health of, 769
Taunton and Somerset Hospital, 472
Tax, proposed, on patient medicines in United States, 1464
Taxation, Imperial, and rates, 1390
Taxes from medical men in Ottoman Empire, 1175
Taxis and injection in treatment of intussusception, 955
Taxonomic Value of the Microscopical Structure of the Stigmal Plates in the Tick Genus Dermacentor (Mr. C. W. Stiles) (review), 451
Taylor, Dr. A. Swaine, the late, Principles and Practice of Medical Jurisprudence; sixth edition (edited, revised, and brought up to date by Dr. Fred. J. Smith), two vols, 1910 (review), 31
Taylor, Dr. C. H. S., and Rolleston, Dr. H. D., case of mollities ossium of 45 years' duration, 436
Taylor, Dr. D., obituary, 132
Taylor, Dr. E. Claude, discussion on influence of parental alcoholism on physique and ability of offspring, 165
Taylor, Dr. G. S., and Thomas, Mr. W. T., specimen of sacro-coccygeal dermoid, 445
Taylor, Dr. G. G. S., and MacKenna, Dr. R. W., case of Darier's disease, 881
Taylor, Mr. H. H., proptosis of the right eye, 940; skiagram of piece of steel from an instrument in the eye of a patient, 666

Taylor, Dr. J., discussion on histopathology of papilloedema, 441; Morgagnian cataract, 806; some ocular and visual conditions in medical cases, 102, 1064
Taylor, Dr. R. S., and MacKenna, Dr. R. W., Ehrlich-Hata remedy for syphilis, 25, 1412
Taylor, Dr. S., case of tumour of the loin, 1208; case of unresolved pneumonia in a man aged 45, 1208
Taylor, Mr. S. J., discussion on histopathology of papilloedema, 441
Tea, chemistry of (chemistry, physiology, and æsthetics of a cup of tea), 44, 46; China, impossibility of plague being conveyed by, 712; plague infection through, no evidence for, 1383; "Pyshan points," 383
Teacher, Dr. J. H., discussion on pathology of embryo in relation to abortion, 444; and Robertson, Dr. Madge E., case of fatal anæmia, sections of the spinal cord and posterior root ganglia from, 1354
Teak, dermatitis from, 895, 903
Teale, Mr. M. A., artificial pupil, 1079; and Coupland, Mr. J. A., case of Hunterian chancre of the left lower eyelid, 1079
Teaspoons, varying capacity of, 635
Teeth, artificial, denture removed from hypopharynx and upper part of the œsophagus, 235; swallowing of, 1399; extraction of, in treatment of extensive caries in children (Mr. J. F. Colyer), 293; Surgery and Pathology of (Mr. J. F. Colyer) (review), 242; teaching importance of, 846; and certain diseases of skin and mucous membrane, relation between, 1206; of school children (Parliamentary question), 709; of workhouse children, 1235
Teeth of children, extension of treatment of, 1669; treatment of, at Hove, 1535
Telephone, tyranny of, 525; exchanges, medical report on employment in (Parliamentary question), 632
Telling, Dr. W. H. M., case of extensive gummatous dermatitis treated by intramuscular injection of salvarsan, 1078; "nodular" fibromatosis an every-day affection, and its identity with so-called chronic muscular rheumatism, 154
Temporal fossa and muscle growth changes in acromegaly, 997
Temporo-maxillary joint, growth changes in acromegaly, 997
Tenement house and its sanitation, 1148; double, in Belfast, 845
Tenements, low-class, high-class tailoring in, 1568
Teratoma, carcinomatous ovarian, case of, 1503
Teratoma of ovary, specimen, 883
Territorial army, 123, 261, 328, 540, 614, 696, 835, 901, 966, 1031, 1304, 1379, 1451, 1663, 1724; sanitary service of, 441
Territorial decoration, 123; officer's receiving 901
Territorial Force, first southern general hospital, Birmingham, 60
Territorial medical officers, books of instruction for (Parliamentary question), 978
Territorials, fair-play for, 1100
Testis, undescended, case of acute orchitis occurring in, after attack of epidemic parotitis and associated with acute delirium, 23
Tetanus, relation of, to quinine, 1368; treatment of, by subcutaneous injections of phenol, 1714
Tetany, relation of, to injections of quinine, 1589; endemic in Gilgit valley (Capt. R. McCarrison), 1575; colonic (Dr. F. L. Langmead), 1137
Tew, Dr. J. S., discussion on the treatment of phthisis by industrial insurance, 733
Text-book of General Bacteriology (Dr. E. O. Jordan) (review), 450
Thalassotherapy, Fifth International Congress on, date and place of meeting, 1472
Thallium acetate, poisoning by, 1461
Thayer, Prof. W. S., venous hum in the epigastrium in cirrhosis of the liver, 1023
Theatres, French, medical service in, 698
Theatrical representation, medical protest against, 1237
Therapeutics, Clinical (Dr. A. Robin) (review), 746; Experimental (Dr. M. Jacoby) (review), 1357; in the Clinics of Berlin University (Die Therapie an den Berliner Universitäts-Kliniken), 1911 (review), 945; and Materia Medica, treatise on, including Pharmacy, Dispensing, &c. (Mr. R. Ghosh and Dr. J. T. Calvert) (review), 745; and Pharmacology, Text-book of (Dr. A. R. Cushing) (review), 1426
Thermal springs of British Columbia, 673
Thermo-anæsthesia in zona, 63
Thermometer case, new, 109
Thesing, Dr. C., Lectures on Biology, 1910 (review), 813
Thief-catcher, "first aid" as, 1113
Thies, Mr. C. W., British Hospitals Association, 1668
Thigh, rodent ulcer of, case (Mr. H. E. Friend and Dr. H. E. English), 579
Thirst and "dry" wine, 823
Thomas, Mr. F., and Coats, Mr. G., peculiar form of granuloma of the retina, 807
Thomas, Dr. J., Le Cancer, 1910 (review), 311
Thomas, Mr. J. Lynn, eye of surgical needles, a new form, 935
Thomas, Dr. M. (obituary), 1677
Thomas, Mr. W. T., discussion on operations for varicose veins, 25; and Taylor, Dr. G. S., specimen of sacro-coccygeal dermoid, 445
Thomas *v.* Barker 604; (leading article), 596
Thompson, Dr. J. S., obituary, 1316
Thompson, Mr. R., and Fripp, Sir A. D., Human Anatomy for Art Students, 1910 (review), 105
Thompson, Mr. W., case of hernia of the small intestine, 26; case of trigeminal neuralgia treated by injection of alcohol, 26
Thompson, Sir W. J., discussion on rheumatism in childhood and in adult life, 741
Thomson, Dr. D., THE LANCET Review of the "Annals of Tropical Medicine and Parasitology" (vol. iv., No. 4, March, 1911), 1380, 1533
Thomson, Dr. F. G., discussion on climatic and balneological treatment of neurasthenia, 664
Thomson, Mr. G., septic mouths of our present-day children, 1029
Thomson, Prof. H. Alexis, boy run over by motor-car, exhibited after repeated operations, 444; discussion on duodenal ulcer, 740
Thomson, Mr. J. A., Outlines of Zoology (review), 745
Thomson, Dr. J. C., the present position of the treatment of plague, 165
Thomson, Dr. S., case of complete stenosis of the larynx from epithelioma, 1076
Thomson, Dr. StClair, appointment to, 184; removal through the mouth of a half tooth-plate impacted in the œsophagus, 940
Thoracic glands, superficial enlargement of, as sign of pulmonary tuberculosis, 118
Thorne, Dr. L. T., the Oliver-Sharpey lectures on heart failure, 1228
Thorne, Dr. W. B., discussion on measles, 1642
Thornton, Mr. G. L., case of an acute infection with splenomegaly and marked lymphocytosis, 1425
Throat, Nose, and Ear, Diseases of (Dr. E. B. Gleason) (review), 1707
Throat and skin, syphilitic affections of, 509
Thrombo-phlebitis, septic puerperal, of pelvic veins, 809
Thrombosis of femoral artery and phthisis in association with recurrent scarlatiniform erythema, 1297; of superior mesenteric vein, 28; of superior vena cava and great veins, case of (Mr. F. C. Davies), 1345
Thrombosis, lateral sinus, operation for, 1645
Thrombosis, Sinus (Dr. J. Wyllie) (review), 1506
Thymus gland, specimens of, 510
Thyroglossal duct, persistent, in child aged 2½ years, 883
Thyroid, lingual, case of, 440
Thyroid, pro- and anti-preparations, action of, 583
Thyroid extract, cretin treated with, 941
Thyroid gland, acute inflammation of, 930, 953; slight general enlargement of, as found in school children (Dr. C. W. Hutt), 875; substance, administration upon occurrence of serum rash and serum sickness in diphtheria (Dr. A. E. Hodgson), 373
Thyroid inadequacy accompanying infantilism, 880; tumour, two unusual cases of, 735; extensive aberrant, 735
Thyrotomy, removal of large subglottic papilloma by, 1644
Tibbles, Dr. W., infantile diarrhœa, 580
Tibia, benign cyst of, 736
Tidman's sea salt, 982
Tidworth, hospital accommodation at (Parliamentary question), 1621
Tidworth, medical attendance on officers at (Parliamentary question), 1045
Tidy, Dr. H. L., relation of acute phosphorus poisoning to acidosis, 19
Tientsin, health measures in (Parliamentary question), 554
Tietze, Dr., condition of the fundus oculi in rupture of the liver, 1387
Tilley, Mr. H., direct bronchoscopy, two cases indicating the value of this method for the detection and removal of foreign bodies impacted in the lower air-passages, 1066; improved form of Hay's pharyngoscope, 1076; plaster casts of an unusual malformation of the upper jaw, 440; portion of a rabbit's bone removed from the right bronchus, 738; specimens illustrating removal of foreign bodies from air passages and œsophagus, 1423; specimen of pedunculated growth on elongated uvula, 1076; tooth removed from the floor of the right maxillary antrum, 738; treatment of malignant stricture of the œsophagus with especial reference to intubation and to radium, 697
Timberg, Mr. R., spinal curvatures and their treatment by physical exercises, 942
Tunisia, cholera in, a correction, 396
Tirard, Dr. N., discussion on after-history of cases of albuminuria occurring in adolescence, 1205
Tissue reaction to radium, 1337
Tissues, changes in, in infective diseases, 485
Title of doctor, 1183
Tiverton Infirmary and Dispensary, financial position of, 505
Tiverton, sanitary certificates at, 1577
Tobacco, dangers of, 1106; influence of, on digestion, 264
Tobacco pipe, seasoned, 1523
Tobacco smoke, filtered, 915
Tobacco smoking, abuse of, followed by dyspnœa (Dr. J. D. Reckitt), 1499
Tobacco substitutes for children, 254
Tolstoy, Count, personal reminiscence, 64
Tonbridge and Tunbridge Wells, meeting in relation to National Insurance Bill, 1722
Tongue, carcinoma of, with extensive involvement of glands, treatment of, 939; malignant growth at back of, 168; tubercle of, primary and secondary, specimens exhibiting, 445
Tonsil, cyst of, 1076; hæmorrhage from, 168; hook to retract anterior faucial pillar during "morcellement" of, 452; left, ulceration of, 441
Tonsils, communication of various infections by, 1609; faucial, anatomy and histology of, 1278
Tonsillar region, excision of, for epithelioma, 939
Tonsillitis, tuberculous cases of, 440
Tooth plate, half, impacted in œsophagus, removal through mouth, 940
Toronto, reorganising health department of, 627
Toronto and McGill Universities, reciprocity in medical teaching at, 626
Toronto General Hospital, foundation-stone laid, 1176
Toronto University and medical licences in Ontario, 627
Torquay Isolation Hospital, 1344
Torrens, Dr. J. A., massive infarction of the renal cortex, 99
Towyn, public health in, 337
Toxæmia, Acute Intestinal, in Infants (Dr. R. Vincent) (review), 672
Toxæmia of pregnancy, some experiments on anaphylactic theory of, 810
Toxicology of filix mas, 1094, 1172
Toxins, invasion of, to spinal cord *vid* spinal roots, histological evidence of, 116; of plague, 1383; in plague epidemic, 1311
Toynbee, Joseph and Arnold, reminiscences and letters of (leading article), 950
Tracey, Dr. H. E., obituary, 1178
Trachea, carcinoma of œsophagus invading, specimen from case of, 665
Tracheolaryngotomy followed by stenosis, tracheolaryngostomy for, 1076
Trachoma, alleged outbreak of (Parliamentary question), 709; and aliens, 1298; (Parliamentary question), 1111, 1181; in England, 1092; in Finland, prevalence of, 754
Tragopogon pratense or goat's beard, case of poisoning by (Dr. F. J. Smith and Mr. H. Candy), 794
Training of Children in Relation to Social and National Welfare (review), 671
Training for rowing, 968; results of, 1101
Training school for nurses, 1315
Transactions of the Medico-Legal Society for the Year 1909-1910, 1910 (review), 311
Transbaikalia, plague in, 535
Transplantation of the fibula, 845
Transplantations, 1308
Transport of London, suggestions as to improvement of, 522
Transvaal Government laboratories, 895
Transvaal Mining Commission, 525, 688
Travail de l'Amphithéâtre d'Anatomie des Hôpitaux: Recherches d'Anatomie Chirurgicale sur les Artères de l'Abdomen (Pierre Descomps) (review), 449
Travelling in tropical countries, 1113
Travers, Dr. E. F., and Maunsell, Dr. D. F., severe burns of the anterior aspect of the chest and neck, with part of the lateral and posterior aspects, three operations for skin-grafting, recovery, 1500

Treatment, Treatise on (Mr. J. L. Chundra) (review), 1429

# Speech
ON
# THE REPORT BY THE EDUCATION COMMITTEE PRESENTED TO THE GENERAL MEDICAL COUNCIL.

*Delivered before the General Medical Council on Saturday, Nov. 26th, 1910,*

BY SIR HENRY MORRIS, BART., M.A., M.B. LOND., F.R.C.S. ENG.

MR. PRESIDENT AND GENTLEMEN,—As the Resolution, which was remitted to the Education Committee on Nov. 26th, 1909, and to which the Report now presented to the Council is the answer, was moved by me, I desire without delay to make some remarks upon the Report so far as it refers to the subjects mentioned in that Resolution. The terms of the Resolution were the following:—

"That it be referred to the Education Committee to consider further the place in the student's career which the preliminary sciences should occupy; and that the committee be requested to frame and submit to the Council a pattern scheme of medical education whereby the required minimum of the several subjects to be included in the curriculum can be adequately studied and the requisite examinations thereon passed within the period prescribed by the curriculum."

In the first place, I wish to express my personal thanks to the committee for the time and trouble it has devoted to the consideration of the questions submitted to it, but at the same time I am compelled to say that in my opinion the Report[1] is distinctly disappointing. In effect, it confirms the *status quo ante*, and if approved and adopted by the Council the result will be to postpone any reformation of the present unsatisfactory state of the curriculum for a period of 10, 15, or maybe 20 years.

I. First, as regards the "pattern curriculum" asked for in the second portion of the Resolution of Nov. 26th, 1909. The reply of the committee is that it could not do as it was asked, and the only reason given for its inability to do so is the very remarkable one that only exceptional candidates could accomplish within the allotted time the study of the full number and amount of the subjects contained within the present curriculum. It was with the object that the committee should consider and report to the Council how this very condition of over-congestion of the curriculum might be obviated that the Resolution of Nov. 26th, 1909, was referred to it. There were two ways in which the congested curriculum could be relieved—namely, (1) either by lightening the curriculum, or (2) by extending the period. The Report does not deal with either alternative. It leaves things exactly as they were. It has made no attempt whatever to adapt the quantity of the contents to the containing space, and the only reason given for its not doing so is that the contents are greater than the space can contain. All that portion of the Report which deals with the statistics showing the length of the curriculum as actually pursued by students under the several licensing bodies, and with the comparison of the curricula of the several licensing authorities, is only indirectly, if at all, relevant to the question referred to the committee. The committee was not asked to draw up a pattern curriculum which would prove acceptable to the majority of the licensing bodies and which would remove the diversity of detail among the curricula. It was not asked even to draw up a pattern curriculum merely as such. What it was asked to do was to draw up a pattern curriculum whereby the required minimum of the subjects included could be adequately and successfully studied within the prescribed period by the average student. The members of the Council knew how improbable it is that any pattern scheme would be accepted by all the licensing bodies, or that diversity of detail among the curricula could be prevented. Diversity of detail in a possible curriculum would be no bad thing. What was the mischief was, that the present curriculum was impossible to the average student. That was the darkness into which the Council asked the committee to throw the light. But the result of the Report is that the students and their parents are left uninformed by the Council of the fact that a nominal five years' curriculum must in reality be one of six and a half or seven years; and the parent who launches his son as a medical student and expects to see him through on the expenditure of from £800 to £1000 has, by bitter experience, to realise that it is only after an additional year and a half or two years of time, and an additional £200 or £400 in cash, that the qualification which he and his son have in view can be attained.

II. Next, as regards "the place in the student's career which the preliminary sciences should occupy." This is the question contained in the first part of the Resolution of Nov. 26th, 1909. The reference was not as to the place in the curriculum, but as to the period of the student's career which the preliminary sciences should occupy—as to whether they should be studied within the period of the curriculum, or previously. The answer of the committee might have been simple and direct, to the effect that the precise period should remain, as in fact it is now, optional, but that if previous to registering, but after passing an examination in general education, the curriculum should be correspondingly shortened by 6 or 12 months. Or its reply might have been that the period should be before the commencement of the curriculum, and that the curriculum, unburdened of the preliminary sciences, should remain at five years. But it was neither the one nor the other. The reply of the committee implies an untruth—of course, quite unintentionally, but still an untruth—that the preliminary sciences must be studied in the five years and in medical schools or in scientific institutions. The wish was father to the thought, and the thought to the implication. The reasons given for this reply are two: (1) that to transfer the subjects from the curriculum and make them part of the course of school education would be to remove them from any effective control on the part of the medical authorities; and (2) that the indiscriminate delegation of these subjects to the school curriculum is a matter which is not ripe for the consideration of the Council. The answer to the first is, that if the preliminary science subjects were made part of the school course, the examination in them would be under the same kind and extent of influence as the subjects and standard of the examination in general education. The answer to the second was given by Huxley in 1889, as well as by the Association of Medical Teachers, and by the writers of an important document 20 years ago. Huxley's[2] statement was, "The student ought to have acquired, as part of his general education, such knowledge of physics, chemistry, and elementary biology as is now demanded of him." In that way Huxley thought the whole curriculum would be given, as he remarked it ought to be, *to special medical subjects.*

The answer given by the Medical Teachers' Association so long back even as 1869 may be seen in a very full "*Report of the Committee on Professional Education*" *of the General Medical Council*, which I fear is but little, if at all, known to the present members of the Council, although several resolutions in the same sense have at different times since that Report was issued been under consideration of the Council. The teachers said[3]: "Every possible latitude of choice, consistent with the supposition of *bonâ-fide* study, ought to be allowed as to modes and places of education; ..... and we are of opinion that no student ought to be forced to learn in any specific establishment anything which he can reasonably be supposed able to learn elsewhere. Thus, if a student prefers to learn botany or chemistry elsewhere than in a medical school he ought, in our opinion, to be free to do so." Elsewhere[4] they express the opinion that chemistry, physics, and botany should be on the same footing as English, Latin, and arithmetic, and that the student should not be called upon to produce evidence of having learnt these subjects in certain particular establishments. Sir James Paget, in his reply to the circular letter issued by the same committee, said: "I think it greatly to be desired that every possible inducement should be offered to students to acquire such

[3] Appendix II., Part I., p. 6, of the "Report of the Committee on Professional Education," 1869, and signed on behalf of the Council of the Medical Teachers' Association by John Simon, President.

[4] Appendix II., Part II., p. 19

knowledge as they need of chemistry, botany, or other natural sciences *in their preliminary education*. The necessity of learning these in medical schools is a very serious hindrance to the more important and practical parts of medical and surgical study."[5] Other eminent teachers might be quoted to the same purpose.

The "document" I refer to above was presented in 1890, and contains the following words underscored with a black line: "*The Sciences as they are now taught for the purposes of the First Examination, whether in Medical Schools or elsewhere, are the proper elements of the preliminary scientific training which should precede the more special and advanced studies, not only of Medicine, but of other scientific professions, and are even gradually becoming recognised as an essential part of a liberal education.*"

Now these subjects, as long as they are retained in the curriculum, either ought to be exclusively studied in a medical school and taught by teachers in touch with the whole course of medical education, or their study elsewhere than at a medical school under specified conditions ought to be recognised. The question may be set aside of their being taught by men in general touch with the medical curriculum as a whole, because whether taught in a medical school or not they are taught by teachers who regard the study of these subjects as the first steps in a science education, and who very little consider their special bearing on other parts of the medical curriculum, whereas the study of organic chemistry in its bearing on physiology and pathology is provided for within the limits of the professional curriculum. But if the study of these subjects is not to be of necessity within a medical school, then on what code of justice is the study of them in a highly equipped secondary school to be excluded? Why are schools like Winchester, Epsom, Dulwich, Bedford, St. Paul's, University College School Frognal Hampstead, to be excluded, whilst polytechnic institutions, and municipal technical schools, and several others mentioned on p. 13 of the Students' Regulations of the General Medical Council are recognised?

Have any of the above-mentioned schools been inspected by the chairman of the Education Committee? Have any one of them been visited, I would like to ask, by one of the self-satisfied gentlemen who signed the "memorial" protesting against the relegation of the teaching of the preliminary science subjects to the school period, which was presented to the General Medical Council in May last—a memorial which was identical in sentiment and phraseology with memorials on the same subject and having the same unfounded objection to the teaching of the preliminary science subjects in secondary schools which were presented to this Council in 1901 and 1902?

The Report of the Education Committee includes two statistical tables (see pages 8 and 9) showing the number of students, with the proportion of successes and rejections, who presented themselves during the years 1908 and 1909 at the first professional examination of the Conjoint Board: (1) from secondary schools; and (2) from medical and science schools. The Report then goes on to say that these tables show that only a very few boys, and those apparently of exceptional ability, were prepared to undertake the first professional examination upon a school study. This was an incorrect and a misleading assumption for three reasons. In the first place, amongst the boys who pass the preliminary scientific (first professional examination) of the University of London as external students are a considerable number from secondary schools, many of who come for examination only in the advanced subjects to the Conjoint Board, and thus are not returned in the tables as entrants from secondary schools, though it had been from secondary schools that they presented themselves for examination at the University of London. In the second place, at least half of the Conjoint Board candidates are graduates or undergraduates of one or other of the Universities, and are therefore exempt from examination in the preliminary sciences at the Conjoint Board. In the third place, there are many who had done a part of their preliminary science studies at secondary schools and the rest in a medical school and are tabulated as having come from the latter. But in so far as the number of candidates from secondary schools, with highly equipped modern sides (as highly equipped as most medical schools, with excellent laboratories and highly qualified teachers) were fewer than might be expected, one cause was the misleading and inaccurate, "so-called," regulations, especially No. 12 on p. 14 of the Council's publication concerning "Registration of Medical Students." These regulations the Report leaves without reference, untouched and uncorrected.

Regulation 10 states that "every medical student shall be registered in the manner hereinafter prescribed by the General Medical Council." Though the word "shall" is used the General Medical Council has no power to enforce registration.

Regulation 11 says that "no medical student shall be registered until ..... he has produced evidence that he has commenced medical study at a University or School of Medicine, or at a Science Institution recognised by one of the Licensing Bodies and approved of the Council."

The Council has no more power to insist on its approval, as a condition of recognition of places of study of the preliminary sciences, than it has to insist upon student registration.

Regulation 12 asserts that "the commencement of the course of professional study" (which includes the preliminary sciences) "recognised by any of the licensing bodies shall not be reckoned as dating earlier than 15 days before the date of registration," whereas there is nothing to prevent the whole period of study of the preliminary sciences being taken and the examination in these subjects being passed before the date of registration or before entrance at a medical school and without having been to a so-called "scientific institution." These regulations are not only misleading and inaccurate—they are directly contrary to the facts. By them the Council is made to appear as usurping a power which belongs to the licensing bodies alone; and sometimes the Council is put into a very ridiculous position thereby.

Take an actual case: A boy, educated at Epsom College, passed first the London Matriculation and then the Preliminary Scientific (M.B.) examination in chemistry, physics, and zoology. After this he was registered, and entered a London hospital. At the end of four years he wanted to enter for the final examination of the Conjoint Board, but was refused on the ground that his year's work at Epsom counted as only half a year towards the five years' curriculum. He next tried to enter for the final examination of a licensing body which follows strictly the regulations of the General Medical Council—namely, the Apothecaries' Company, and was refused because he could not be signed up for a five years' course at a recognised medical school. As a last resource he applied to the University of London, and was admitted without demur. Having passed the examination and obtained his degree he inquired of the Registrar of the Council whether he could now register as a practitioner, although he had been registered as a student for four years only. Did Mr. Allen then refer him to these regulations of the Medical Council and say to him "No! You have not complied with our conditions of registration"? Why, of course not; on the contrary, Mr. Allen had to register the young gentleman and to admit that the Medical Council has not the power to refuse to register a person who had duly passed his final examination.[6]

As long as these regulations remain as instructions of the Medical Council injustice will be done (*a*) to the students, (*b*) to the parents, and (*c*) to those secondary schools which have spent thousands of pounds in building and equipping science laboratories.

(*a*) There is injustice to the students, because the tendency of the regulations is to take boys away from school discipline and control before it is really necessary to do so, and to bring them to a medical school where they are not under the guidance of masters and are beyond the "general education" atmosphere of school life. On this point I will quote from a letter written by the high master of St. Paul's School.[7] He says: "The intention of the Council was doubtless right. It meant to prevent the premature specialisation in medical work. But the effect has been precisely the opposite of that intended. Instead of inducing the student to prolong his 'general education,' it tempts him (by the unfounded fear of losing a year) to go to a medical school at the earliest possible moment."

(*b*) There is injustice to the parents, who are misled by the form of the statements issued by the General Medical

[5] Report of the Committee on Professional Education, 1869, p. 187.

[6] See a letter from Dr. Burton, THE LANCET, Oct. 8th, 1910, p. 1103.

[7] See letter from Dr. Hillard, THE LANCET, Oct. 8th, 1910, p. 1103.

Council into the idea that preliminary science study at school does not count towards the medical curriculum at all, and that the Council can enforce a full period of five years between registration as a student and registration as a practitioner. I know of one parent who sacrificed a valuable scholarship which his boy had obtained at his school in order to place him at a medical school earlier than he otherwise would have done, being unaware of the Council's inability to insist upon the observance of its own regulations.

(*c*) There is injustice done to the secondary schools which have a highly developed "modern side"[s] because the boys are induced to leave to go to a medical school at a time when it would be beneficial to them to remain a year longer at school, and when by doing so they would bring credit and distinction to their school. Moreover, other secondary schools would be stimulated to develop their "modern side" if these misleading and misguided obstacles were removed from their way by the Council.

For these several reasons I beg to move the following Resolution; and as the subject is one of immense importance to general practitioners and to other parents and guardians, who intend giving their sons and wards a medical education, I have asked Dr. Langley Browne, the senior of the Direct Representatives for England and Wales, to second it:—

That as the Education Committee in their report of Nov. 22nd, 1910, express views in favour of retaining the preliminary sciences (chemistry, physics, and biology) as subjects of the medical curriculum, it be referred to the committee to consider and report to the Council as to the best way of amending the regulations of the General Medical Council in regard to the registration of medical students with the objects (1) of making those regulations consistent with the report and with the powers of the Council; 2) of making clear the distinction between regulations which must be observed and recommendations made for the students' guidance; and (3) of the advisability of altering or deleting Regulation 12 on page 14 of the regulations printed under date June 1st, 1910.

# A Clinical Lecture

ON

# ULTRA-CHRONIC PULMONARY TUBERCULOSIS.

*Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton, on Dec. 14th, 1910,*

BY H. BATTY SHAW, M.D. LOND., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—This subject has been chosen for two reasons. The first is, that though it is known that pulmonary tuberculosis may be a chronic disease, so far as general impressions indicate, it is not common knowledge that it may exist for so many years as to justify the term "ultra-chronic"; no doubt many members of the profession can give examples drawn from the records of their patients which may possibly equal, and even exceed, those brought forward in this lecture. Little effort, however, has been made to publish details in a series of cases of the longevity of patients who are afflicted with tuberculosis of the lungs. The reason for this is not far to seek, for until a few years ago the term used to describe pulmonary tuberculosis was "consumption" or "phthisis." This term was primarily a purely clinical one, and indicated that there was disease of the lungs which led to wasting of the body. With the discovery of the tubercle bacillus by Koch in 1882, a new and more pathological significance was given to the wasting produced by disease of the lungs. For some time an effort was made to put the new wine into old bottles, and the attempt produced considerable confusion, which unhappily still exists. Practitioners are to be found to-day who, in obedience to the older teaching, will tell the friends of a patient who is suffering from pleurisy or some other suggestively tuberculous affection of the lungs, that possibly the disease will some day turn into "consumption"—i.e., the patient may begin to "waste" and be ultimately carried off by the malady. We know much more now of the early manifestations of pulmonary tuberculosis, and recognise how the so-called primary pleurisy may be but the early stage of pulmonary tuberculosis. Our text-books, however, still teach the duration of "consumption," and a medical student believes that, as a rule, pulmonary tuberculosis and "consumption" are identical, and that the average duration of the latter—something between two and four years—also expresses the duration of the former. This is a mistake, but cannot be remedied until figures are forthcoming which at least will point to a much greater duration. Facts which are drawn from the out-patient letters of this hospital will show how great a need there is for a revision of the subject of the prognosis in pulmonary tuberculosis.

The second reason is, that owing to the admirable arrangements by which the records of the out-patients who have attended or who are attending this hospital are preserved and rendered accessible, it is possible to trace the condition of the lungs of patients who attending during my eight years of office have also years ago been under the care of some of my senior colleagues in the same department.

Owing to the now well-recognised fact that so much can be done by residence in a special hospital, and more still in a sanatorium for pulmonary tuberculosis, to instruct sufferers from this malady in the hygienic rules which are necessary for their own and their fellows' welfare, as many out-patients as possible who are not too advanced in disease are admitted for the special instruction and treatment. It is a common experience, however, to find that patients suffering from early pulmonary tuberculosis are prevented by circumstances or caprice from availing themselves of these advantages. They elect to remain as out-patients whilst their letters allow them to do so, and then are lost sight of for years or altogether. They may present themselves again, but unfortunately in so advanced a stage that they may no longer be recommended for admission. But some may be found to come back for treatment who have not advanced in their disease, and having ascertained this fact again disappear, maybe for years, to reappear with the same evidence of quiescence of the disease existing in their lungs. It is to this last group that attention is called in the present lecture.

The consideration of these cases will be found profitable in that it will show how extremely chronic this malady is in a certain proportion of cases, and it will also be of economic advantage, as it may lead to a less hasty decision to offer to all cases of pulmonary tuberculosis the costly advantage of special treatment. So long as these patients are instructed in methods by which they may avoid infecting their fellows they are quite able to discharge their duties in life, and apparently with little risk of advancing their disease by such action.

At the outset, it would seem advisable to come to some agreement upon what may be called ordinary clinical pulmonary tuberculosis; this will vary according to the experience of each physician and his point of view. Merely to set a reasonable limitation to the lecture, only those cases will be considered who have suffered from pulmonary tuberculosis for five, or more than five, years, the maximum limit reached by one of the list of patients being 39 years, and from this list it will be possible for each of you to set your own limits as to what may be called ultra-chronic pulmonary tuberculosis.

Another question arises as to what criteria should be adopted as proof of pulmonary tuberculosis. In the first place, it is desirable that actual tuberculosis should be established: following modern developments, only those cases will be referred to in which the expectoration has been found to contain tubercle bacilli. This organism was discovered by Robert Koch 28 years ago, but many of these cases have revealed what has later proved to be pulmonary tuberculosis, years before such tests as examination for tubercle bacilli in the sputum were applied to them. The earliest case in the list to be tested in this way is one originally under the care of Dr. Percy Kidd, who fixed the nature of the patient's malady by finding the organism in the expectoration in 1892. During the last four or five years each one of the patients whose reports are now submitted for examination has been proved to be tuberculous in this way. In some cases the only objective sign of pulmonary mischief

[s] I use the term "modern side" merely to indicate schools where practical teaching and laboratory work are carried on. I am aware of the fact that in some of these schools a certain amount of classical work is done by the boys in their forms even though their chief work is the study of sciences.

was the presence of these organisms in the sputum. The result is that out of a total of 9428 patients who presented themselves to me for treatment up to Dec. 10th of this year, 1532 have been found to expectorate tubercle bacilli. It is, of course, possible that more than this number are tuberculous. Rightly or wrongly, use has been made only of the cases of those patients who recently or years ago presented themselves for symptoms or signs maybe merely suggestive of tuberculosis, and who during the last four or five years, when sputum examination has been made a routine practice, have been found to yield expectoration charged with tubercle bacilli. No doubt the objection will be raised that it is not right to argue that such cases were tuberculous from the beginning; possibly they suffered from non-tuberculous bronchitis to begin with and tuberculosis was superadded at a later date, maybe as a result of sitting for hours in the waiting-room amongst patients who were tuberculous. Rightly or wrongly again, this objection has been put aside and a patient who years ago may have suffered from "pleurisy," "hæmoptysis," "pneumonia," "inflammation" or "congestion of the lungs" of some weeks' standing, or even of "fistula in ano," or may have had "chronic cough" or "bronchitis" and subsequently has been found to bring up sputum containing tubercle bacilli is considered to have had tuberculosis for at least as many years as such symptoms have existed. Further, patients who presented "signs" of pulmonary disease years ago, such as apical râles, basal dulness, and weak breath sounds (unilateral in most part), and who in the last four or five years have been shown to be tuberculous by bacteriological examination of the sputum, are also considered to have suffered from tuberculosis from the date at which such signs were discovered. To those who sympathise with such views this lecture may appear acceptable; to those who do not the considerations brought forward will appear fallacious. Experience shows, however, that despite the fact that a considerable number of physicians still hold that the above symptoms and signs may be non-tuberculous in their inception, more probably they were tuberculous; parents who have suffered for years from a simple "winter" cough or from bronchitis and emphysema will be shown to present family histories which indicate what havoc has been made of their children, who have died from tuberculosis of the lungs, meninges, &c., even when they have been suckled at the breast or have been fed on cow's milk which has always been boiled before use. In view of these facts, it is wiser, not only from the point of view of the immediate companions of such people but from the point of view of the public, to consider that the above signs or symptoms are indicative of present tuberculosis. It is believed that human beings may have tuberculous lesions which are shut off from the rest of the system; they carry the organism, but apparently beyond having a localised focus of disease they are not sufferers so far as symptoms are concerned; they constitute a form of "carriers of tubercle bacilli"; their expectoration, if they have any, may contain tubercle bacilli. It may also be advanced as possible that healthy people have tubercle bacilli deposited in some part of the respiratory tract, but without producing any lesion, constituting a more true form of "tubercle carrier." Such cases have been reported as occurring amongst physicians who work in institutions where many tuberculous patients congregate. The fear that such a possibility may weaken the interest aroused by a consideration of the duration of life of some of the patients presently to be considered may be set aside, to a very great extent, for in those cases actual cough, with the discharge of sputum, has been a feature of each case; not only have tubercle bacilli been found in the sputum of these cases, but signs are present which justify the belief that they are suffering from genuine tuberculosis of the lungs, and that it is not a question merely of accidental occurrence of tubercle bacilli in the sputum of people who are non-tuberculous. It may be said that no patient upon whom a necropsy has been performed in this hospital during the last 18 months, and in whose sputum tubercle bacilli had during life been demonstrated, has been found to be free from tuberculosis of the lungs.

### ANALYSIS OF CASES.

Of the 1532 patients who have been discovered at the last visit to the hospital to show tubercle bacilli in the sputum, and to have present signs indicative of pulmonary disease 303 are found to have had the disease for five or more than five years. But in this number it must be admitted that there are included some whose tuberculosis for some years existed, so far as can be ascertained, only in some part of the body other than the lungs—e.g., they may have first of all suffered from tuberculous dactylitis, adenitis, or tuberculous hip disease. This lecture is based upon facts which form part of a project to show the duration of pulmonary tuberculosis under the influence of out-patient treatment only. The number of 303 cases includes some who have had the benefit of in-patient and sanatorium treatment. Excluding these latter and also those whose tuberculosis expressed itself first in some system other than the pulmonary one, 212 cases are left, and from this number of patients observations are presented which will show how chronic may be the course of pulmonary tuberculosis subjected to the very trifling help, so far as the direct treatment is concerned, afforded in out-patient practice. These patients have succeeded in many cases in maintaining families, and, as their occupations will show, under conditions which are the very reverse of those which would be chosen to help arrest the disease.

Opinions will differ as to which cases may be called ultra-chronic cases, but the figures of Table I. will allow of individual opinion being exercised.

TABLE I.—*Analysis of 212 Cases of Pulmonary Tuberculosis of a Duration of Five Years and Over, showing the Number of Cases for each Year up to 39 Years.*

| Duration in years. | Number of cases. | Duration in years. | Number of cases. | Duration in years. | Number of cases. | Duration in years. | Number of cases. | Duration in years. | Number of cases. | Duration in years. | Number of cases |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 5 | 25 | 10 | 18 | 15 | 11 | 20 | 9 | 25 | 5 | 30 | 2 |
| 6 | 23 | 11 | 12 | 16 | 5 | 21 | 2 | 26 | 1 | 31 | 1 |
| 7 | 22 | 12 | 7 | 17 | 5 | 22 | 2 | 27 | 2 | 34½ | 1 |
| 8 | 14 | 13 | 9 | 18 | 7 | 23 | 2 | 28 | 2 | 39 | 1 |
| 9 | 13 | 14 | 7 | 19 | 2 | 24 | 1 | 29 | 1 | | |

Obviously no claim may be made in this lecture to originality as regards the established fact that pulmonary tuberculosis may be a very chronic malady, but the generality of us are obliged to be content with the observation that such chronicity is indicated by the term of two to four years or thereabouts which has been found by past workers to express the average duration of chronic cases of consumption. Table I., however, shows that something like one-seventh of all cases of pulmonary tuberculosis, using a more preferable term and one which is not at all synonymous with "consumption" or "phthisis," may live for more than five years, even as many as 39, without any more effective remedies than those used in the out-patient department of this hospital, each of which is but symptomatic in design. It is necessary to call attention to the fact that only in some cases do the figures expressing the duration of life indicate the period elapsing between the onset of the symptoms and death. In a large number of the cases life has lasted longer than the last time each patient appeared for relief at this hospital. In some cases this last appearance was eight years ago, and in others during this present month, but in all cases life had lasted at least as long as the years indicated in the column headed "duration of life." There is a considerable falling off of the figures indicating a survival of more than 15 years, and probably no one would object to call all those cases which have survived this limit examples of ultra-chronic pulmonary tuberculosis; there are 53 of these cases representing about one-thirtieth of the total number of 1532 cases. Locked up in this comparatively small number are all the secrets which underlie the cure of pulmonary tuberculosis, for it may reasonably be said that processes which can secure to the individual such a long survival of infection of the lungs by the tubercle bacillus are exactly the ones which medicine should endeavour to secure as therapeutic agents.

On looking through Table II. some interesting points will be observed. The patient who survived his first illness, which is now held to be a suggestion of pulmonary tuberculosis, viz., "pleurisy," was able to present himself this year at the hospital—i.e., about 34½ years from the date of the pleurisy; his occupation is that of a "packer." Another patient, who is a bookkeeper, survived "pleurisy" 30 years; and another patient, who was a needlewoman, survived the same malady for the same number of years. A salesman, whose first

departure from health was the development of a "fistula in ano," survived pulmonary tuberculosis for 15 years, and probably had this latter complaint at the time of development of the fistula. Quite the most remarkable of the whole list is the case of No. 272, a housewife. Her first visit was made to the hospital in the year 1891, at the age of 40 years, and she came under the care of Dr. Percy Kidd. She gave the history that during the previous 20 years she had had cough and also during the same period hæmoptysis. Expiration was prolonged at both apices, and there were dulness and crepitations over the middle lobe of the right lung. Tubercle bacilli were detected in the sputum in 1892. Similar signs were found by Dr. S H. Habershon in 1896, and they were more advanced in 1898. In 1903 the same signs were made out, but in addition there were friction sounds heard at the left base; tubercle bacilli were again present in the expectoration. The patient, now 61 years of age, was invited to come to this lecture for the purposes of demonstration, but wrote to say that she was unable to come as she was confined to her room with a severe cold; "until quite recently her health had been fairly satisfactory." Judging by the history she had had symptoms of pulmonary tuberculosis for at least 39 years, signs of the disease had been present 19 years, and tubercle bacilli were found in the expectoration 18 and 7 years ago.

The occupation of these patients shows that indoor employment does not necessarily preclude survival with the disease during a considerable number of years, because all but 8 of the 53 patients followed vocations within doors.

From the economic point of view this table is of value, for it shows that there need be less hesitation in allowing patients who have undergone special treatment in sanatoriums or hospitals to return to the work they have followed prior to admission, although such work entails spending their time indoors. It is possible, and indeed probable, that these patients effected considerable harm amongst those with whom they lived during so many years of unrecognised disease. One marked example was met with in No. 1631. This man had had a family of 13 children, of whom only three survived; five children had died from definite tuberculosis, including a daughter aged 21 years, who died from pulmonary tuberculosis. It is impossible to ascertain what the remaining five children died from, but quite probably tuberculosis was a factor. The presumption is that this man had infected the various members of his family who had succumbed to tuberculosis, as his wife was free from symptoms and signs of the disease.

To those of our profession who hesitate to accept that these 53 patients had suffered from pulmonary tuberculosis from the time in which they stated they first had pulmonary symptoms, the list will appear unsatisfactory. In order to satisfy them a table (No. III.) is now submitted of five patients who have survived pulmonary tuberculosis for 15 and more years, as shown by the signs figured on their out-patient papers by my predecessors who in former years had charge of them. During the last four or five years these patients have been shown to be tuberculous by the discovery of tubercle bacilli in the expectoration.

TABLE III.—*A List of Five Cases of Ultra-chronic Pulmonary Tuberculosis who have Survived 15 or more Years after the Discovery of Clinical Signs of the Disease, the Evidence of Tuberculous Signs being Documentary.*

| Register number. | Occupation. | Year in which first signs were detected and observer. | Year in which corroborative signs were last noted and extent. | Duration in years of physical signs. |
|---|---|---|---|---|
| 501 | Housewife. | Râles at both apices (Dr. Percy Kidd), 1888. | 1903; three lobes involved. | 15 |
| 8931 | ,, | "Scattered sibili" (Dr. Percy Kidd), 1891. | 1907; four lobes involved. | 16 |
| 2648 | Electric car conductor. | Left pleural effusion (Dr. Percy Kidd), 1890. | 1908; two lobes involved. | 18 |
| 4167 | Talloress. | "Hæmoptysis" and doubtful signs (Sir J. Kingston Fowler), 1881. | 1905; one lobe involved. | 24 |
| 10591 | Ironmonger. | Dulness left base (Sir J. Kingston Fowler), 1885. | 1910; four lobes involved. | 25 |

This small series of five cases, with the possible exception of No. 4167, shows that tuberculosis of the lungs may reveal signs at the beginning and end of periods of 15 to 25 years. Each patient had pursued an indoor occupation, except No. 2648, who had probably been advised to take up the work of a 'bus conductor in order to get open air.

This lecture must be concluded with an expression of the hope that others will be found who will supply evidence of as great or greater chronicity in patients suffering from pulmonary tuberculosis. The more such evidence is accumulated the better it will be for the subject of the treatment of the malady, for it will give support to those who, whilst giving fullest credence to the benefits to be derived from sanatorium treatment, feel that after hygienic rules have been learnt, the patient may in suitable cases carry out the cure of the disease in his or her ordinary surroundings and whilst carrying out the duty of a wage-earner.

# SOME OF THE MORE RARE CAUSES OF THE ACUTE ABDOMEN.[1]

BY WILLIAM HENRY BATTLE, F.R.C.S. ENG.,
SURGEON TO ST. THOMAS'S HOSPITAL.

AT intervals we meet with cases presenting acute abdominal symptoms, which resemble rather closely some of those manifested by the more common examples of perforation of the hollow viscera, so that a diagnosis of one of these accidents may be wrongly arrived at. When the abdomen is opened, however, the lesion expected is not found, and we have to search for changes which may indicate that a more unusual and perhaps unsuspected disease is present.

*Acute Hæmorrhagic Pancreatitis.*

In this disease, which is most difficult to diagnose, the symptoms are referred to the upper abdomen, and, as they are very urgent and accompanied with much pain, early operation is generally permitted if suggested to the patient. Yet on opening the peritoneal cavity there may be nothing abnormal presented at first sight, whilst the blood-stained fluid usually present, being small in quantity, may be overlooked as a sign of disease. And in the early stage of this illness not only may the effusion of blood be of small quantity and possibly unnoticed, but there may be no fat necrosis, the only sign which can absolutely be relied on at the time. A good illustrative case was the following.

A widow, aged 57, was sent to me at St. Thomas's Hospital by Dr. G. Brebner Scott, of Brixton, for an acute abdominal illness on Feb. 23rd, 1909. At 6 P.M. on the previous day she had complained of great pain in the abdomen. She said that it began on the right side and spread rapidly to the left, and also extended upwards to the right lower ribs. Vomiting came on at once, and she could keep nothing down subsequently. Her bowels had acted naturally the previous morning. There was no history of biliary colic or of injury, and she had been quite well until this illness. She was a well-nourished woman, who still complained (at 6 P.M. on Feb. 23rd) of abdominal pain. This was now general, all over the abdomen. She looked ill, had a pulse of 110, and a temperature of 101° F. The abdomen was distended, generally hard to the touch, and very tender, but not specially so in the iliac fossa. On percussion there was patchy dulness, both in front and on the lateral aspects of the abdomen, but not in the flanks. No abnormal swelling could be felt, but the wall of the abdomen was fat. Her tongue was dry; the bowels were not acting. Operation was decided upon, and an incision made on the right side through the rectus muscle. When the peritoneum was opened a good deal of blood-stained fluid escaped. There was no lymph on the peritoneum, but the omentum appeared somewhat thick and infiltrated, whilst in two or three places there was fat necrosis. The pancreas appeared harder than usual and enlarged. The gall-bladder was normal; no stone could be felt either in it or in the biliary passages. The small intestine on the right side was distended. The peritoneum was washed out with normal saline solution and the incision was closed. The abdomen was closed because the amount of fluid did not appear to increase during the operation, and the peritoneum was quite clean. She was relieved by the operation, but on the following evening her temperature rose again to 100° and pulse to 136, so the incision was reopened, more fluid evacuated, and a drainage-tube put in. The following day Cammidge's test (*c*) was reported as positive. The patient was very ill for some days, and at one time appeared very flushed, weak, and despondent. Drainage was continued until March 10th, about a fortnight, after which she gradually improved. It is not necessary here to give any further details of the case. She left hospital on April 20th, and has since had good health, having quite recovered.

This case is encouraging inasmuch as it was a successful one; unfortunately, successes are not numerous in the practice of any one surgeon, however large his experience. There have been five cases under my care within recent years, all of which were submitted to operation, but this is the only one in which a full success can be claimed. But even when operation does not save life, it relieves of the agonising pain which is so very distressing in most. The history of alcoholism was not obtained in all. As a rule, the movements of the body were more free than they are after acute perforations of intestinal ulcers. In one case the patient (a female lunatic) was found to be lying on her side, and that position is not assumed in many acute abdominal conditions.

Fitz wrote of acute pancreatitis a few lines to which I may draw attention: "Acute pancreatitis is to be suspected when a previously healthy person or a sufferer from occasional indigestion is suddenly seized with violent pain in the epigastrium followed by vomiting and collapse, and in the course of 24 hours by a circumscribed epigastric swelling, tympanitic or resistant, with slight rise of temperature." I should say that the patient is commonly an adult of more than 40 years of age, well nourished, and even fat, apparently in good health until seized with a sudden attack of severe abdominal pain. Dr. C. R. Box has pointed out to me that the majority are females, and that this corresponds to some extent with the greater frequency of gall-stones in women.

On examination I have found that the abdomen has been more resistant generally than it should have been, but not rigid. There has been a diffused superficial tenderness, especially on unexpected light palpation; the general resonance over the abdomen has been rather patchy in character without evidence of free fluid, whilst the movements during respiration have been good. In all the pulse has been rapid, there has been anxiety, and not infrequently a flushed face, whilst there has been a rise of temperature. As Dr. A. Elliot reminds us in his interesting paper on this subject[2] (to which I am indebted), the cause of the rapidly fatal ending in acute hæmorrhagic pancreatitis is not always easy to determine. It has been put down to hæmorrhage, but many cases cannot be so explained, for in a considerable number the amount of extravasated blood has been comparatively small. Nor is it probable that the sudden disturbance of the whole or part of the pancreas is a sufficient explanation. Some have ascribed the fatal result to shock.

The other acute abdominal conditions which most clearly resemble it clinically are: (1) perforations of the stomach or duodenum; (2) perforations of the appendix; (3) acute intestinal obstruction; (4) acute cholecystitis with perforation of the gall-bladder; (5) acute irritant poisoning; and (6) very rare conditions, such as embolism of the mesenteric artery, rupture of a liver abscess or hydatid, &c. Of these it is most commonly put down to *perforation of the stomach*, but in the *anterior* perforation, although we have the sudden onset of intense pain, there is rigidity of the rectus muscles in the epigastric region, loss of liver dulness, with the rapid effusion of free fluid down the right side of the abdomen. When a *posterior* perforation of the stomach has occurred the symptoms are mostly referred to the lesser sac, so that they may be more difficult to differentiate. In gastric perforations the vomiting may, but does not usually, continue, and may indeed be absent, whilst there is a history of gastric symptoms pointing to chronic disease of the stomach or duodenum.

In *acute appendicitis*, although the pain is referred to the umbilicus at the beginning of the attack, within a short time there is tenderness in the iliac fossa and the pain moves to that part. The muscles become rigid over the iliac fossa,

[1] Abstract of a paper read before the Derby Medical Society on Nov. 8th, 1910.

[2] Transactions of the West London Medico-Chirurgical Society, October, 1910.

and localised dulness on percussion may be demonstrated, whilst if the appendix is placed unusually high on the right side, although the resemblance to acute hæmorrhagic pancreatitis is more close, there is still the differentiating rigidity and localised dulness.

In *acute intestinal obstruction* high up, possibly from a band, the pain is paroxysmal, vomiting very urgent, and the initial shock marked. Fæcal vomiting occurs early and obstruction is complete, no flatus being passed. Abdominal distension is but slight if any is present.

*Gall-stone colic and cholecystitis* are not infrequently diagnosed, more especially as there is so often the history of gall-stone colic in the past life. In the more acute cases of perforation of the gall-bladder a tender swelling may have been noticed in the gall-bladder region for some time—perhaps for days—before the onset of urgent symptoms.

Cases of *poisoning* rarely lead to any real difficulty. In acute metallic poisoning the purging is a prominent feature, and the discovery of the poison in the vomit places the diagnosis beyond doubt. In ordinary food poisoning there is usually more than one patient affected; diarrhœa is present as well as the vomiting, and cramp-like pains are a frequent accompaniment.

In acute hæmorrhagic pancreatitis if the abdomen is opened within 24 hours the amount of blood-stained fluid will be small, and may be supposed to have run from the external wound into the peritoneum; again, at this stage, it may be difficult to find any of the yellow points of fat necrosis. In any case in the adult where nothing is found in the more usual places to account for acute abdominal symptoms, search should be made for these areas, which are of small size, somewhat irregular outline, and yellowish-white in colour. I have been struck with the sodden state of the great omentum in some early cases, even when there have been very few points of fat necrosis visible. It has been of a greyish appearance, and has lost elasticity. There may be no evident swelling of the pancreas. If nothing is found which explains the sudden acute attack, it will be best to put in a drainage-tube for a few hours—for I can but think that some of the cases of abdominal section which have been closed "because nothing was found," have been of this nature, and without free drainage for a time the result of interference in most of them is worse than useless. A discharge which at first is of a reddish colour and varying amount will generally come away through the tube; this becomes of a yellow tint, and possesses a peculiar mawkish smell, and must not be permitted to accumulate within the peritoneal cavity, however small in quantity it may be. These patients are rarely good subjects for abdominal section, and I believe better results will be got on the average from simple drainage than from a more elaborate operation, such as incision of the pancreas, &c., possibly with drainage of the gall-bladder. Most of them will not stand the additional manipulations required, with the prolongation of the period of anæsthesia; it is possible, however, to do more if the patient is seen early in the attack, is in fair condition, and not too fat. The ideal operation is to incise the pancreas, with due regard to the duct and main vessels, and establish a direct route for the drainage preventing the escape of fluid into the surrounding peritoneal cavity, as in cases of rupture of the organ. Unfortunately the action of the secretion from the gland, if much escapes, is very destructive on the tissues with which it comes in contact, and if the flow is profuse you will find it difficult, or even impossible, to prevent actual digestion of parts.

### *Acute Dilatation of the Stomach.*

This is a rare condition, the origin of which is sometimes doubtful; it may follow an operation involving the peritoneum. An attack starts with copious fluid vomiting, epigastric pain and distension, which becomes diffused; the action of the bowels is irregular; signs of extreme collapse are present. Towards the end of a severe case complete atony of the stomach may lead to cessation of the vomiting. Of physical signs, the most valuable, when it is present, is succussion, but it is important to remember the possibility of the occurrence of such a condition in the acute abdomen. Unless relieved by evacuation of the stomach contents it usually proves rapidly fatal. The extreme distension of the abdomen and generally severe condition may lead to a diagnosis of acute peritonitis, or if there is constipation intestinal obstruction may be thought to be present. I will give two contrasting examples, one occurring in the course of an acute pulmonary attack, the other secondary to an abdominal operation and associated with general intestinal distension.

(I.) On Jan. 21st, 1903, I was asked to see, with Dr. Michael J. Bulger, a patient aged 15 years. The history of the case was as follows. Dr. Bulger was called to see her on the 19th, when she complained of pain under the left breast on breathing, which was increased by taking a deep breath; there was slight expectoration tinged with blood. Over the painful area there was some dulness, increased vocal resonance, and crepitation on respiration. On the 20th the patient was much easier. Temperature, 102° F.; pulse, 96; could take food easily, bowels acting. She was the subject of angular curvature of the dorsal spine, the result of old tuberculous disease. On the 21st she began to vomit at about 7 A.M., the vomited material being of a bilious character and yellow in colour. The bowels acted at 8 A.M. The pain in the side was much better, but the constant vomiting masked all other symptoms. Temperature, 99°; pulse, 80. Nothing relieved the sickness. The abdomen was retracted, dull all over, and without tenderness on pressure. At 6 P.M. she was rather collapsed, the vomiting continued, and now she was bringing up a black, tenacious fluid. She had complained of no pain since the vomiting came on, but the abdomen was becoming distended. About 11.30 P.M., when I saw her with Dr. Bulger, the abdomen was somewhat distended, but not markedly so, dull on percussion all over the front and down the left flank to Poupart's ligament. No dulness was present in the right flank. A well-marked thrill of fluid could be felt in the lower part and to the left. There was no rigidity. The pulse was rapid, face pale and sunken, tongue black and dry, whilst there was frequent vomiting of a black, tarry fluid. An incision in the middle line showed a greatly distended stomach, the lower margin of which passed down to the pubes; it was bluish in appearance and flattened. All the intestines were empty. There was no free fluid. Distension apparently ceased at the third part of the duodenum, and no pressure could empty the contents of the stomach along this part. A tube was put in, and the opening sutured to the abdominal wall. Much fluid was drained off from the stomach by this tube, and vomiting ceased; but very little relief was afforded, and the patient died on the following day, apparently from exhaustion.

(II.) This is the other example. A woman, aged 27 years, came under my care at St. Thomas's Hospital, sent to me by the late Dr. Heath of St. Leonards-on-Sea, on Nov. 7th, 1901, for a swelling in the abdomen, which had been noticed nine years, and was said to be increasing. On the 12th cœliotomy was performed, the diagnosis of ovarian cyst confirmed, and the tumour removed in the usual manner. On the first and second days after the operation the patient's pulse was about 110, and the temperature rose from 101° to 103° F. The abdomen became increasingly distended; there was no vomiting beyond that directly following the anæsthetic. A week after the operation there was evidence of slight suppuration in the abdominal wound, and pus was evacuated with a director. There continued to be great distension of the abdomen and much discomfort. On the 21st Dr. C. R. Box saw the case with me. The epigastric area was then very prominent and a ringing coin sound could be obtained over this area and extending downwards to the iliac crests; marked succussion was elicited on shaking the patient; there was no vomiting. Lavage of the stomach was commenced and carried out twice daily from this time. 26 days from the operation parotitis developed, associated with a septicæmic temperature and severe diarrhœa, and for some time this was uncontrollable. Anti-streptococcic serum was given; a marked rash followed two days after its administration, but it was without apparent effect on the disease. The distension of the abdomen did not appreciably diminish, and with a high temperature and the diarrhœa it continued for about three months; much œdema of both legs and the lower part of the abdominal wall supervened. Some peristalsis in the region of the umbilicus was occasionally seen, and the stomach still showed the physical signs of dilatation. On August 12th, 1902, the patient left the hospital. The gastro-intestinal functions had become normal, but the œdema in the lower part of the body, due (presumably) to thrombosis of the inferior vena cava, was still present. Seen again in January, 1903, her general health was good, though evidence of thrombosis persisted, there being some œdema of the ankles, with dilatation of the veins over the lower part of the abdomen.

The subsequent history of the second case is very interesting. The patient was readmitted to St. Thomas's Hospital under my care on Nov. 19th, 1907, for another abdominal swelling. It was stated that her general health had been good until a fortnight before, but that during that time she had suffered from pain in the stomach and swelling, but no vomiting. The abdomen was a good deal distended and tense on admission, the superficial veins dilated, chiefly in the lower part, and there were numerous lineæ albicantes in the same region. A dull rounded area was present reaching almost to the umbilicus from the pelvis. This was fluctuating and tender, whilst around it the intestines were distended and tympanitic. Her temperature was slightly raised. She was kept in bed for some time in order to give the inflammatory state a chance of quieting down, but the distension did not appreciably diminish. On Dec. 4th an incision to the left of the mid-line was made, and an inflamed ovarian cyst was removed. The pedicle was long and had been twisted three times from left to right, this rotation probably resulting from the movements of the over-distended pelvic colon. The cyst was very adherent to the omentum, but not suppurating. It was an ordinary multilocular cyst. The gut was very much distended, the sigmoid being about 5 inches in diameter when examined in the wound. The intestine was not punctured, as the condition was regarded as temporary in character. Much flatulent distension of the abdomen continued, not involving the stomach; many remedies were tried, but until the employment of the interrupted current late in December no definite effect appeared to have been produced by them, but the distension suddenly subsided on the 25th of that month. There was no suppuration or rise of temperature after the operation. The unusual amount of distension of the intestines present at the time of the second admission and the difficulty in getting rid of it after operation are especially interesting in a patient with this history. On this occasion there was no suppuration either before or after the operation, yet the distension was extreme, and suggested that the nervous element was an important factor in its causation. The rapid recovery on the use of the interrupted current confirms this view. We know how marked the "reflex" effect may be sometimes of an injury to the abdomen unattended with obvious lesion, also the great distension of the abdomen which may ensue on the mere application of a ligature to the neck of a hernial sac in the operation for radical cure. In a patient once under my care a condition of rapid distension of the abdomen with pain, vomiting, and a temperature of 103·6° F. ensued, with a collapse which excited alarm. Appropriate remedies soon produced a change for the better and the case ran the usual aseptic course without further symptoms.

The cases narrated above are both of them examples of acute dilatation of the stomach but present many points of contrast. In the first case the stomach had become a mere fluid-containing sac with a thin wall, which at the time of the operation was lying over the front of the intestines and gave a dull note on percussion across the middle line, an area which is resonant in all other conditions of the acute abdomen. There was most certainly no gaseous accumulation, and until quite the last stage there was no distension of the abdomen. It is difficult to account for the distension unless we accept that it was a paralysis due to some toxic condition associated with the patch of inflammation of the left lung found by Dr. Bulger when he first saw the patient. Spinal deformity has been noticed in other cases of acute dilatation, but when not associated with the application of a plaster jacket it is difficult to understand how it could have much influence on the production of such an acute and fatal affection.

Dr. W. B. Laffer collected a series of 217 reported cases, and of these 38·2 per cent. followed operations, usually one on the abdomen. The earlier notes of Case 2 were published by Dr. Box and myself in THE LANCET on account of its rarity, and as an encouragement in the treatment of such desperate conditions. We are inclined to put its occurrence down to some toxic absorption from the wound, although the amount of suppuration was neither acute nor extensive. It is probable that she owed her recovery to the fact that the distension was general and not absolutely confined to the stomach and duodenum. Dr. Laffer, from an analysis of his series of cases, writes: "The pathology and *modus operandi* of acute dilatation of the stomach and gastro-mesenteric ileus is not definitely known, but the experimental, clinical, and pathological evidence points to a primary innervation disturbance affecting the gastric nerves or their centres in the brain or cord. It has not been proved that the compression of the duodenum by the root of the mesentery is the primary cause of the so-called arterio-mesenteric ileus." Thus agreeing with Dr. Box and Mr. C. S. Wallace in their opinion.[3]

*Some Neuroses which may Cause Symptoms of Urgency.*

*Hæmorrhage from the stomach.*—No surgeon has any doubt that operative treatment is sometimes absolutely necessary in hæmorrhage from gastric or duodenal ulcers. It may be the only means of saving life, but the indications for its performance should be clear and definite. In some cases it may be possible to find and deal with the exact cause of the hæmorrhage; in others it will only be possible to treat the distension of the stomach (by gastro-enterostomy) on which the occurrence of the bleeding so frequently depends. It may be the wiser plan, when possible, to perform the operation of gastro-enterostomy, although the local trouble has also been directly treated.

In dealing with these cases it may be advisable to remember the possibility of the hæmatemesis being of hysterical origin, for such a condition is always amenable to medical treatment, and in my opinion should not be submitted to operation under any circumstances. The history of the case here given not only supports this statement but shows in a marked degree the ills that may follow ill-advised interference.

A woman, aged 29 years, was sent to me by Mr. Frank Boxall of Rudgwick in September, 1902, for varicose veins of the left leg which were causing her pain when standing. She was admitted to St. Thomas's Hospital (Mr. T. Guthrie was house surgeon), and Trendelenburg's operation with excision of some of the more prominent veins in the calf was performed. In her past history it was stated that she had been in another hospital a short time before for symptoms which were regarded as indicating the presence of a gastric ulcer. One night she developed acute symptoms, which were supposed to have been due to perforation of the ulcer, and an exploratory incision was made in the epigastric region by a surgeon, who found nothing but a normal state of the stomach; there had been no perforation. From the history this attack was supposed to have been hysterical. During her stay in hospital this opinion was confirmed by the fact that in the earlier days after her admission, when she was looking somewhat anxious in the face, she again gave an exhibition of perforation. She complained of acute pain in the epigastrium, the upper abdomen became suddenly distended, and the muscles appeared tense. There was, however, no change in her appearance, the pulse-rate, or temperature, and other symptoms were not in agreement with perforation; we had also the history to go upon, and the condition quickly improved when no special treatment was given. This patient left St. Thomas's about a fortnight after the operation for the veins, but returned in 1904 on account of hæmatemesis. She was vomiting daily, without any relationship to food, large quantities of fluid, in which there was a good deal of blood of dark colour, evenly diffused. In spite of the fact that this continued for a month without cessation, she showed no signs of anæmia, and always presented a smiling face to the world. No particular drug was given to arrest the bleeding, which was regarded as of hysterical origin. When the hæmatemesis had ceased for a few days and she had become bright and cheerful she was sent home. In about three months' time she was sent back to the hospital with another attack of hæmatemesis of similar character, from which she recovered in from three to four weeks, and returned to her home quite well. It was some months before anything further was heard of her, and then it appeared that she had again developed hæmatemesis when the influence of the hospital had passed off, and this time her friends sent her to a hospital "where there was a surgeon who would operate." Her next admission to St. Thomas's was on July 19th, 1905, when she was found to have a fæcal fistula, which communicated with the transverse colon and was situated at the lower part of a scar, through which, it was stated, her

[3] THE LANCET, vol. ii., 1901, p. 1259.

stomach had been operated on. We were informed by letter that although no ulcer or cause for the hæmorrhage was found at the examination, it was "thought" by the surgeon that there was an ulcer in the duodenum. She said that after the operation she did very well until the tenth day, when it was found that the milk which she was taking came through into her dressings. A second operation was done and the milk no longer came through the wound, but in ten days' time fæcal matter appeared when she took medicine, and fæcal fluid came through if she had an enema administered. The abdomen was opened in the middle line below the old scar and a lateral anastomosis of the large bowel above and below the fistula done. There were many adhesions. Recovery from this operation was quite uneventful, the fistula was allowed to close and, when she left the hospital, it was of about the size of a wooden match. She left at her own request. Readmission was sought in January, 1906, because she said that the escape of gas from the fistula was troublesome and caused offence to patients when she was nursing them. There was now a fistula of about the size of a cedar pencil, and as the bowels were acting well there appeared no reason why this should not be permitted to close. Accordingly a dressing was placed over it, and secured in position by means of broad strips of rubber strapping. The fistula closed to some extent, but we could not feel sure that it was not kept open in some way by mechanical means at the command of the patient. A smaller dressing was then applied, and this was covered and held in position by means of collodion. After this was applied she complained of excruciating pain and said that she could not possibly bear the agony of it. It was not, however, removed for a week, when the fistula had completely closed. I may perhaps mention that the fistula was found to have become distinctly larger after she had had a bath without the presence of a nurse; this was before the collodion was applied.

We were for a time under the impression that the case was now completed, but in March, 1909, the patient again came into the hospital during the cleaning of a charitable institution to which she had gained admission. A fæcal fistula had formed at the site of the former one, and she refused to have anything done with a view to closing it. When questioned as to the formation of this fistula she said that an abscess had come and had burst, leaving the fistula behind it, but there is a strong possibility that it did not form in this manner. If it had been closed, and this would soon have occurred under simple treatment, for there was a free normal passage for the fæces, she would no longer have been eligible for the institution in which she had now been received. I may add that her expression was that of a neurotic, and the diagnosis of hysteria was confirmed in many ways.

It was surely unnecessary to perform a gastrotomy for the relief of hæmatemesis in a case with this history. Gardini[4] has given the account of a case of similar origin. A girl, aged 22 years, had suffered from gastric symptoms for six years, and almost daily vomiting of blood for five months or more; in that instance the mucous membrane of the stomach is said to have been tinged, hypertrophic, and of a red colour, but there was no evident cause for the hæmorrhage. The patient was apparently cured by the operation. Gastric hæmorrhage has sometimes a purely nervous origin; sometimes it is simply a form of vicarious menstruation and has a relationship to the menstrual periods, as well as to emotional and constitutional disturbances and injury.[5]

Those of us who are engaged in doing much operative work must recognise what is almost a disease amongst a certain class of patients, chiefly those with abdominal symptoms—the desire for operations. It is not very unusual to see many scars on the abdomen and yet a continuance of symptoms.

*Enterospasm.*—By this term is now recognised a condition in which there is a spastic contraction of the muscular wall of some part of the intestines; there is no obvious structural change in the bowel, and the phenomena are usually regarded as being dependent upon some abnormal action of the nervous mechanism. The spasm may give rise to symptoms of varying intensity, from those of chronic constipation to such as simulate acute intestinal obstruction. Dr. H. P. Hawkins drew attention to the condition in 1906,[6] and I will quote from some of the conclusions he then set down. "Symptoms usually manifest themselves in patients during the active period of life; they appear with about equal frequency in the two sexes. The individuals affected are usually of a neurotic type and often of sedentary habits." Opportunity for direct observation of the spasm of the bowel does not often occur, but Dr. Hawkins thinks that the colon is more often affected than the small intestine. The pain in the subacute cases is sometimes localised in the right iliac region, and so appendicitis may be simulated.

I need here only consider the severe cases giving rise to symptoms which suggest the necessity of immediate operative interference. Sometimes the resemblance of the condition to intestinal obstruction of organic origin, or even to general peritonitis, may be so close that the mind of the observer is left in doubt as to the right diagnosis, and exploration of the abdomen will be the only sound course to pursue. Points which will be helpful in arriving at a decision are the presence of the trouble in highly strung, nervous individuals, and a history of previous attacks of abdominal pain similar in character and which have passed off without operation.

In a recent case operated on for me by the resident assistant surgeon, Mr. L. E. C. Norbury, the patient was a woman aged 40 years, for whom I had removed gall-stones about two years previously. Her symptoms were those of acute intestinal obstruction, and the spasmodic contraction affected much of the small intestine. She is a typical neurotic in appearance. I have met with the condition as a mere localised affection of the splenic flexure in more than one instance; here the patients have been overworked and anxious men of over 45 years of age.

A CASE OF

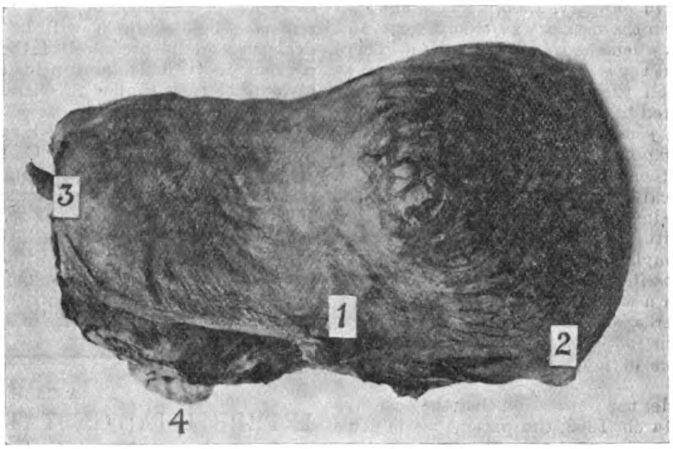
# INTERSTITIAL GESTATION AT THE THIRD OR FOURTH MONTH WHERE THE SAC WAS REMOVED UNRUPTURED WITH THE BODY OF THE UTERUS BY ABDOMINAL HYSTERECTOMY.

BY ARTHUR H. N. LEWERS, M.D. LOND., F.R.C.P. LOND.,
SENIOR OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

THE patient, a married woman, 29 years of age, was admitted into the London Hospital on July 17th, 1910. She had been married for three years, and had had one child 11 months previously and one miscarriage three months after marriage. She had suckled the baby up to a fortnight before her admission. Soon after the confinement there was an interval of amenorrhœa lasting six weeks, but after that the periods came on and continued to occur regularly (although she was suckling) up to the middle of April, 1910. Since that date she had "seen nothing." Ten days before admission to hospital she had noticed a lump in the lower abdomen on the left side. Three days before admission she was seized during the night with sudden attacks of severe pain in the region of the lump. When she was brought up to the hospital she was evidently acutely ill, but as the cause of her illness was uncertain till a careful history had been obtained she was admitted in the first instance on the surgical side. When the circumstances were more fully investigated the case was thought to be probably obstetric, and it was therefore transferred to the obstetric wards in the early morning of July 18th, where I saw her at about 2 A.M. The pulse was then 120 and the temperature 97·5° F. She was suffering from very acute pain in the lower abdomen, but she was not anæmic, nor was there any vaginal bleeding. The mass in the left iliac region was felt, but could not be very thoroughly examined as there was great tenderness, and the muscles were rigid. On vaginal examination the cervix was soft, and the mass to the left appeared to be closely connected with the uterus (which was enlarged) and perhaps part of it. The history of

three months' amenorrhœa and the condition of the cervix with some enlargement of the uterus made it very probable that she was pregnant; while the absence of any vaginal bleeding, and the character of the pain, with such marked tenderness, were against regarding the condition as one of miscarriage. I thought probably the condition was one of ectopic pregnancy, although the fact that the patient was not anæmic showed there could not have been any serious internal hæmorrhage. It appeared to me that an exploratory laparotomy was the best course, and accordingly I at once proceeded to operate. On opening the abdomen just a little free blood was seen. The body of the uterus was enlarged, and to the left of it, and separated only by a shallow groove, was a rounded swelling larger than the body of the uterus itself, about the size of two fists. The left Fallopian tube, which was normal, could be traced up to this, and the condition was then recognised as one of interstitial gestation. Supra-vaginal hysterectomy was then performed in the usual way, the body of the uterus being removed together with the unruptured gestation sac. The various steps of the operation were a good deal hindered by the fact that the intestines were much distended. Both sets of uterine appendages appeared to be normal and were not removed. The patient suffered a good deal from shock during the first 24 hours after the operation. She then rallied well and made an uninterrupted recovery.

FIG. 1.



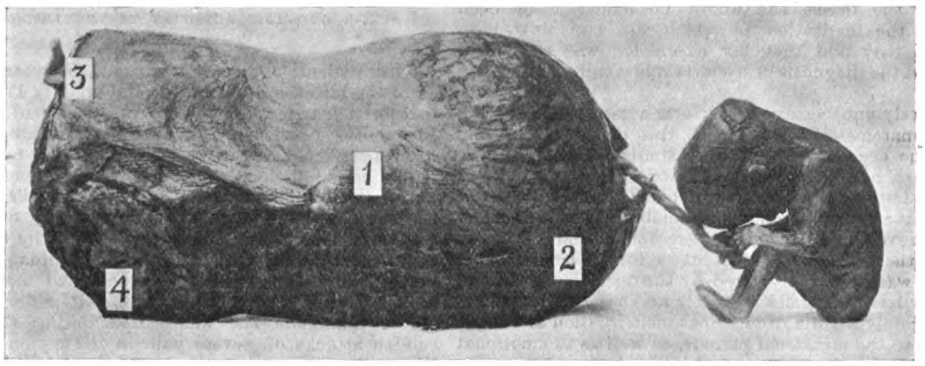
Anterior aspect. A large ectopic sac is seen at the left cornu. The hypertrophied round ligament (1) is inserted directly on to the sac. To the outer side at (2) is seen the stump of the left tube and the ovarian vessels. (3) The normal right round ligament. (4) Decidual lining projecting through internal os at the level of amputation.

*Description of the parts removed.*—The specimen consists of the body of the uterus and an adjacent pregnant sac, and has the appearance of a bilobed tumour. The two lobes are of unequal size, and are separated from one another by a shallow groove. The smaller of the two lobes is the enlarged empty body of the uterus, lying below and to the right; the larger, lying above and to the left, is the ectopic sac. From the cavity of the uterus at the level of amputation projects a rich decidual lining (marked 4 in the photograph). The ectopic sac is globular, and is 4 inches in diameter. Over the whole of its peritoneal surface large veins are seen ramifying, especially in the neighbourhood of the left tubal stump, and close to the contiguous left border of the uterus. At the lower and inner pole of the gestation sac, and a little external to the above-mentioned groove, is seen the thick hypertrophied left round ligament (1) inserted directly into the sac, and in marked contrast to the small round ligament on the right side (3); a distance of 4 inches separates the two round ligaments. At the upper and outer pole of the gestation sac is seen (2) the stump of the left tube and ovarian vessels ligatured close to the sac and thus preserving the ovary. Anteriorly no breach of surface is seen on the convex glistening peritoneal aspect of the sac, but posteriorly there are one or two faintly eroded areas where the peritoneum has lost its lustre, and serum exudes through at these areas on pressure. This has evidently been the source of the small amount of blood found free in the peritoneal cavity when the abdomen was opened.

These anatomical relations show that the case is certainly one of interstitial pregnancy on the left side of the uterus, since the left round ligament is inserted directly on to the sac on its anterior aspect, and the normal unaltered Fallopian tube lies well to the outer side of the gestation sac.

On opening the sac subsequently after hardening, the wall of the sac at its highest point is seen to be very attenuated in thickness. A "window" cut out here passes through a thin slice of placental tissue, and exposes a normal fœtus of three months' development, or perhaps rather more, connected by its umbilical cord to the placenta, which occupies the bulk of the inner surface of the sac. Sections taken through the sac wall demonstrate the presence of muscle and early placenta.

FIG. 2.



Anterior aspect. The gestation sac has been opened at its thinned-out apex, traversing placental tissue. A well-developed fœtus (third to fourth month gestation) connected by its umbilical cord to the placenta on the inner surface of the sac is seen outside an artificial opening made in the sac. The sac was about the size of two fists.

I am indebted to Dr. R. D. Maxwell, obstetric registrar at the London Hospital, for the above description of the specimen, and for superintending the preparation of the photographs herewith reproduced.

*Remarks*.—Interstitial ectopic pregnancy is much the rarest variety of tubal gestation. It is also one of the most

dangerous, because, owing to the walls of the sac being formed of uterine tissue, pregnancy proceeds generally to a more advanced date than is the case in the other varieties of tubal gestation. When, therefore, the sac does rupture a large and often fatal amount of blood is rapidly lost owing to the relatively large size of the vessels. Thus, in this variety of ectopic pregnancy, once rupture has occurred there is much less chance of having the opportunity to operate in time to save the patient. It is, of course, quite true that in the commoner kinds of tubal pregnancy—the isthmic and the ampullar—a fatal quantity of blood may be lost; the loss, however, owing to the smaller size of the vessels concerned, takes place more slowly, and, if the case is seen fairly soon, the probability is that the operation will be successful. It is obvious how important it is, therefore, in cases of interstitial pregnancy, to recognise its presence as soon as possible and to operate without delay. In the case narrated above the diagnosis was not absolutely made before the abdomen was opened. It was evident, however, that the patient was seriously ill and in great pain, and that there was an abnormal swelling to the left of the uterus and closely connected to it. In the presence of such conditions it is undoubtedly the best thing to perform laparotomy, and ascertain exactly what is wrong. A point of some interest in the history of cases of interstitial gestation is that usually there is persistent amenorrhœa up to the time when the case comes under observation, whereas in other forms of tubal pregnancy more or less irregular hæmorrhage is found to have occurred in the great majority of the cases. A point requiring consideration during the operation in interstitial pregnancy is as to whether it is possible to excise the sac, or whether it is better to perform hysterectomy. No doubt in some cases, where the sac is small, it may be safely excised. When, however, the sac is as large as it was in the case just recorded, I feel sure the safest plan is to perform hysterectomy.

Upper Brook-street, W.

## A NOTE ON THE CARDIAC DIASTOLIC SOUND AND IMPULSE.

BY THEODORE FISHER, M.D. LOND., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

COMMON though a diastolic sound audible at the apex of the heart is, there seems to be some confusion in the minds of many as to its significance. When sufficiently loud to attract the attention of the comparatively inexperienced auscultator mitral stenosis is frequently diagnosed. Not long ago I met with a striking illustration of this. It fell to my lot to examine a considerable number of children in whom disease of the heart had been diagnosed at some previous period, generally a year or longer before, and in several of the children a presystolic murmur, thought to indicate the presence of mitral stenosis, had been noted. When I listened it was evident that in many of the cases in which a presystolic murmur had been heard no organic disease was present. In these cases the so-called "presystolic murmur" no doubt had been a diastolic sound which had disappeared.

A murmur which is heard at one time by a medical man and not heard at a later period by another is generally assumed to have been a so-called "functional" systolic murmur or possibly an exocardial sound. It probably is true that in the majority of instances a murmur which attracts attention and then disappears is systolic in time. A diastolic sound, however, is also a sound which may be present for only a short period, and consequently when we are informed that a murmur has been previously heard which we fail to detect, it seems to me that the possibility of a diastolic sound having been at one time present and assumed to be a murmur should not be forgotten.

The hearing of most of us, no doubt within certain limits, differs in its power to note the occurrence of sounds of various grades of intensity or of pitch. Some probably are comparatively sensitive to high-pitched sounds, others to those of low pitch. Exocardial sounds, for example, may easily attract the attention of some, while a dull diastolic sound will appeal more readily to others. To me a diastolic sound of faint character is so commonly heard that I might almost describe it as a normal sound of the heart. Even a sound which should be sufficiently well marked to be heard by the majority seems to me to be not infrequently heard over the hearts of people in the very best of health. While, however, this appears to me to be true, it is scarcely necessary to remark that the diastolic sound is most distinct in various abnormal conditions. But these conditions are often only passing. The presence of a well-marked diastolic sound audible over the heart towards the end of some cases of typhoid fever and its disappearance during convalescence is well known. But during ailments of slighter character this sound, although not uncommonly present, may not so often attract attention. An ill-defined febrile attack of a few days' duration may in a child be quite sufficient to lead to the appearance of the sound, and it is frequently heard in comparatively chronic conditions of ill-health, such as dyspepsia or anæmia. The listlessness and unusual inactivity of a temporarily debilitated child may lead to the suspicion on the part of the relatives that something may be wrong with the heart, and there is a danger probably that the discovery of a diastolic sound may lead the medical practitioner to share this view. Less commonly restlessness rather than inactivity may give rise to concern in the mind of the parent, and over the heart when restlessness is a sign of temporary ill-health a diastolic sound may also be heard.

Here it may be mentioned that when a diastolic sound is well-marked a diastolic impulse is also present which can be felt by the hand placed over the heart. A tracing can be taken with a cardiograph or with Dudgeon's sphygmograph of such an impulse. The pressure employed, however, should be slight. Under too great pressure the wave due to the diastolic impulse does not appear on the tracing. This ease with which the wave may be obliterated renders its impulse to be felt much more easily by the hand than recorded by a tracing. Fig. 1 represents a tracing taken from over the

FIG. 1.

A cardiographic tracing taken with Dudgeon's sphygmograph showing a diastolic wave preceding the rise due to systole.

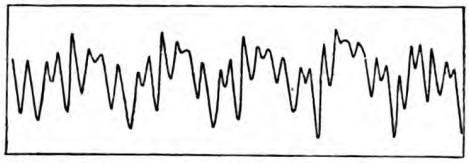
heart of a boy, aged 11 years, who had never suffered from rheumatism or from pains in the joints. He was brought to be examined by his mother on account of restlessness. He appeared to be intelligent but nervous. On auscultation a dull but very distinct diastolic sound was audible at the apex of the heart. Associated with the sound was an impulse of which a tracing was taken. Five years later the boy was again seen. He was then a healthy, well grown lad working on a farm. No trace of anything abnormal could be detected in his heart.

Although a diastolic sound is commonly present in association with temporary ill-health in which the heart probably suffers, it is perhaps most marked in cases of organic disease, but in those cases the sound may be strangely inconstant. That is to say, it may be distinctly audible one hour and not the next. The character of the impulse and the character of a cardiographic tracing, as might be expected, change with the alteration of the sounds. Over the heart of a man suffering from alcoholic disease of the heart within the space of half an hour I have obtained two tracings, one a normal cardiographic tracing, and the other showing a well-marked abnormal rise in association with the presence of a diastolic sound. In mitral stenosis the presence of a diastolic sound

distinct from the presystolic murmur is frequently observed. The sound need not, however, be limited to the apex like the true presystolic murmur, but may be widely heard over the heart.

In a discussion as to the probable causation of this diastolic sound I do not propose to enter, but it may be mentioned that the sound apparently may arise either in the left or in the right ventricle. When the sound is best heard at the apex it probably arises in the left ventricle. When more widely heard it may arise in both ventricles or in the right only. Over the right ventricle, as at the apex, the distinctness with which it is audible varies from time to time. Over the right ventricle the diastolic sound is not uncommonly best heard, and sometimes heard only at the moment that expiration ceases and inspiration begins. This is the moment at which an intermission of the pulse is frequently noted to occur in children. Although, as has previously been mentioned, it is not intended to discuss the

FIG. 2.



Tracing of a heart-impulse taken with Dudgeon's sphygmograph when a diastolic sound, part of a bruit de galop, was present. The sharply pointed wave preceding the notched systolic wave represents the position of the diastolic sound in the cardiac cycle. Respiratory undulations are also recorded in the tracing.

causation of a diastolic sound, possibly the fact that it frequently occurs when inspiration is commencing to lend its aid to diastole of the ventricles may be considered to support the view that a diastolic sound is in some way connected with active diastole. A fact which may also be urged in support of such a view is the occurrence of a diastolic sound in association with hypertrophy of the heart. The presence of the sound in the large heart of Bright's disease has frequently been the subject of comment. Another variety of hypertrophy in which the sound occurs is the hypertrophy associated with adherent pericardium in children. Here the sound may sometimes be so prolonged as to

FIG. 3.

Tracing taken from the same heart-impulse with Marey's cardiograph, showing the rise of the apex in diastole during intermissions. When this tracing was taken no diastolic sound was audible, and the wave before the systolic wave is absent.

be readily mistaken for a presystolic murmur. Fig. 2 shows a tracing taken from over the heart of a boy, aged 14 years, who died with a very large heart associated with adherent pericardium. During life a well-marked diastolic sound, in this case of bruit de galop rhythm, was audible. It may be interesting to compare the tracing taken over the heart when a diastolic sound was present with one taken when the heart was intermitting, but no diastolic sound was audible (see Fig. 3). In the second tracing there is absence of the sharp pointed wave preceding the systolic wave, a slow rise being present in its place before the systolic wave which follows an intermission.

The above remarks are intended chiefly to refer to the possibility of the sound being incorrectly thought to indicate the presence of valvular disease. The sound, however, always seems to me to be possessed of more than ordinary interest, and when one considers its frequency it is perhaps surprising that it has not been more often a subject for careful investigation.

# BRITISH HEALTH RESORTS FOR FOREIGN INVALIDS.[1]

BY NEVILLE WOOD, M.D. DURH.,
HONORARY PHYSICIAN TO THE KENSINGTON DISPENSARY AND CHILDREN'S HOSPITAL.

AT the very threshold of my somewhat novel topic I am met by the necessity of surveying the subject as a whole rather than dealing, as I might otherwise have done, with certain of its more important details. This is due to the fact that even propositions apparently so elementary as that our British health resorts offer substantial benefits to foreign invalids or would gain anything from their presence will require some argument in their support. The policy, indeed, of most of the municipalities concerned would seem to exhaust itself in efforts to keep the Briton from foreign countries, rather than to bring the foreigner to ours. And while on this topic, I cannot refrain from protest against the appeals—short-sighted, if patriotic—issued presumably by responsible authorities, against our sending patients abroad rather than to this or that British resort. Considerations of dignity apart, do not such urgencies suggest an admission of weakness, an admission for which there is certainly no occasion? Much better—even for the ends in view—would be a frank recognition of the conditions under which a certain proportion of the invalids of any country do benefit by being sent out of it. By stating categorically the classes of patients unsuitable for home resorts, these writers would, it seems to me, improve their own position, as they would thereby strengthen the hands of practitioners in allotting to British stations the vast remainder of patients, who would be rightly sent there. Certainly, no well-informed British physician could conscientiously endeavour to dissuade all, or nearly all, his patients from seeking health in other lands, and I suggest that the proper way to redress an adverse balance is to take measures to attract those foreign invalids for whom it can be shown that the therapeutic resources of our country are peculiarly well adapted.

I have contended elsewhere (and towards the acceptance of this view at home and abroad the considerations urged in this paper are an additional contribution) that continental health resorts should not be regarded as competing with British health resorts, nor British with continental. They are, and that for immutable reasons, complementary to each other. And it is my conviction that when we succeed in making the inhabitants of the European mainland as well aware of the specific advantages of our stations as we are of the indications for theirs, there will be a free interchange of invalids, instead of, as now, a movement practically in one direction, and that away from our shores.

Let me illustrate by a single example the absurdity of the present position. In one of the most distant of the continental spas coming within the orbit of expatriated British invalids it is shown by statistics that 1 patient in every 30 hails from Great Britain, whereas at one of our leading spas it is estimated that less than 1 per 1000 comes from all the countries of the Continent put together. This is a state of things likely to continue as long as the literature dealing with our health resorts is written in English only, and as long as it passes over in silence the advantages, actual and potential, of our stations to foreigners in search of health and recreation. It will, in fact, continue just as long as we are content to allow foreign physicians and laymen to suppose that there exist in our islands no spas or climatic stations of the highest rank. In a well-known German manual describing the health resorts of Europe there is no mention of any in England. Again, in a similar French publication, in its forty-ninth year of issue, whereas six pages are allotted to Spain, two are considered appropriate for Great Britain, while various errors and omissions sufficiently indicate the absence of competent revision. It has, however, recently come to my knowledge that the editor of one of these books endeavoured, but without success, to procure

[1] A paper read before the Balneological and Climatological Section of the Royal Society of Medicine on Dec. 14th, 1910.

in London an authentic account of British spas. That, at least, was a manifestation of interest, and when I met with another in a request for a sketch of our seaside resorts as an addendum to the German translation of my little book "Spa Treatment," and received, further, the generous offer of a French translation of a work on British spas, it seemed to me the time had come to bring the whole subject before the council of this section, and to offer a paper, both to elicit criticism from the general body of our members and to enlist their active assistance in the task of making widely known abroad the climatic and balneary resources of Great Britain. Criticism is advisedly placed first; for it is not unlikely that I may, on the one hand, have overlooked strong points in, so to speak, the case for Great Britain; while, on the other hand, if the medical men practising in any of our health resorts are of opinion that there is no room for the introduction of foreigners, I should be disposed, in anything written for continental journals, to lay little stress on the particular stations considered suitable only for patients of our own nationality.

I think, however, that there can be but few of our professional health resorts which would not find the presence of a cosmopolitan element beneficial. In addition to the cash brought to its coffers (though possibly an almost negligible quantity for some years) an advantage to the station would be that the prospect of a steady increase in the number of patients from a fresh source would stimulate the zeal of the local authorities in effecting improvements, for I believe that in some instances these authorities would be more inclined to give heed to foreign than to native criticism, lay or medical. And, be it said, it is the absence of those amenities which are demanded by foreigners that forms one of the excuses of Britons for their annual pilgrimage abroad. The medical men, collectively, would be conscious of the incentive afforded by wider scope in the fields of scientific investigation and of practical therapeutics. But the watchword for practitioners, no less than for spas, is prestige, and a full measure of prestige will never be gained until British mineral water stations have added international fame to national repute.

Turning now to another aspect, I think that the writer who desires to trace the lines on which we may proceed to place before the foreigner the advantages of the British Isles for some invalids—and their disadvantages for others—best fulfils his task by abstaining from over-much refinement and by confining himself as far as possible to statements likely to meet with general acceptance. That must be my excuse for adhering, on the whole, to the conventional and inclining to the methods of dogmatism. I will begin, then, with the general proposition that when health fails in one set of surroundings common sense suggests an entire change; while in its application to my immediate purpose I think attention may justly be called to the fact that in many ways our island differs more from all the continental countries than do they from each other. It follows, therefore, that in the numerous instances when change of environment is demanded, whether for its own sake or as an adjunct to treatment, balneary or climatic, the health resorts of Albion merit the attention of clinicians in very many lands. And since our foreign *confrères*, like ourselves, sometimes fail to obtain sufficient control over patients who remain within motor distance of home or business, it may be suggested that the plan of placing a strip of water between an invalid and his cares is not less advantageous for dwellers on one side of the Channel than on the other.

Passing from the general to the specific, and dealing with the limitations as well as the merits of British spas, it may be taken as certain that not many patients will be sent to them from the European mainland for an intensive bathing course alone, our cool climate not serving as an auxiliary to that form of treatment. Nor will large numbers come solely for a drinking course, since we possess no waters of types which are not well represented on the Continent. Regarded purely from the climatic standpoint, however, every part of Britain has the decisive advantage of being at its best for a special purpose just when most of the continental stations, and certainly all the spas (unless perhaps St. Moritz), are at their worst. That purpose is active exercise in the fresh air, and that season includes the greater portion of July with the whole of August—the most crowded months of the summer season. Now it might be supposed that the point I have just made does not deserve so much emphasis, for in England we commonly overlook this aspect of spa treatment. But in Germany and Switzerland conditions exist which compel physicians, not infrequently, to have recourse to the manœuvre suggested; and I have some reason for thinking that France must shortly follow suit. It is true that foreign spas offer to the enfeebled superior incentives to the less severe forms of physical exertion, but a long and really brisk walk becomes a trying ordeal therein the hotter months even for persons in the best of health. The cooler climate of Britain, on the other hand, favours all kinds of outdoor exercise, including, of course, the best of all—the Royal and ancient game of golf.

Taking all these considerations together, we at once perceive that the categories of foreign invalids for whom our spas are typically suitable include those who thrive in a relatively cool climate and are able to walk well; those who in association with complete change derive benefit from baths which are neither very hot nor taken in close succession, and, of course, those whose maladies are held to be tributary to the waters we possess—that is to say, the muriated, sulphuretted, indifferent, earthy, and alkaline sulphated. Such waters, as everyone here knows, are well represented respectively at Llandrindod, Harrogate with Strathpeffer, Buxton, Bath, and Cheltenham; while there are iron springs at many spas, strong salt water at Woodhall, and brine at Droitwich. All of these resorts are sufficiently well-equipped balneologically, and in their different ways compare not unfavourably with the corresponding continental spas.

There is a charge which has so often been levelled at our spas that it cannot be left unnoticed. Stated bluntly, it is that they are intolerably dull. Denial, admission or apology, must be left to other writers. Comment sufficient for my purpose is that, taking together all continental spas, there are not more than five which can definitely be described as gay. In a large proportion of the remainder tranquillity reigns. Yet these essentially restful resorts are visited annually by thousands of invalids—by invalids who do not desire the amusements of a great city or the excitement of Monte Carlo. It is from this sufficiently large army of health-seekers that recruits may be drawn for a pacific invasion of our island.

Uncertainty of weather, or, in other words, excessive rainfall, is an apparently more formidable objection, but I would point out that on the European mainland also a spa season may be spoilt by persistent downpour. Such was the case this year throughout the continent, and last year in the northern stations. It must be admitted that the month of June is more often wet and cold with us than abroad; but in July and August less rain falls in the eastern division of England than at some of the stations of Western Europe. In the West of England the rainfall is no doubt considerable, but in summer it is not quite the drawback that might be supposed, for during the showers the patient can sit or promenade on a veranda, while even if driven indoors he need not, and should not, close the windows. If proper open-air galleries were erected at British spas patients coming for a serious cure would be rendered practically independent of rain; the existing structures, known as winter gardens, might well be called summer penances.

As a concluding observation on the subject of British spas from the international point of view, I suggest that whereas for Britons they may be regarded as mineral water stations, with climatic advantages, for foreigners their rôle is rather that of climatic stations, with the advantage of mineral waters.

I trust that enough has now been said to establish my contention that our spas can render important services for a goodly number of patients from beyond the seas. When the sketch comes to be filled in, and the specific merits of the separate stations are properly defined, it will, I think, be found that their utility stands out in still more marked relief. For these purposes a volume is now under consideration, with authoritative monographs written locally, and the whole collated by whatever chapters may appear to be necessary. Entire candour will, I hope, be the key-note of this work, for spa literature without that quality is fit only for the scrap heap.

Passing on now to our seaside resorts, I believe them to possess for foreigners many advantages which, if not so well defined, are even wider in range; these resorts may, in fact, be regarded as alternatives for some continental spas, as well as for climatic stations, inland and maritime. It has been shown by Frankenhäuser that many of the inhabitants of

central Europe, and especially those who are anæmic, nervous, or scrofulous, suffer in the height of summer from the extreme dryness of the air which persistently overworks the evaporative function of the skin. He explains that the benefit derived by such persons from a course of spa treatment is largely due to the re-hydration effected by a series of immersions in mineral water baths. During the bath, and after it, the hygroscopic salts pass into the superficial layers of the epidermis and remain lodged there; and thus, as he expresses it, the patient becomes clothed in a gossamer mantle of deliquescent salts, which, by checking evaporation from the skin and neutralising the effects of abrupt changes of temperature, places the overstrung organism in a state of relative physiological repose. This action is supplemented by the air at most of the German spas, rendered relatively moist by afforestation and other factors, while it is carried a stage further by the still greater humidity of the seaside resorts.

Anyone reflecting on Frankenhäuser's carefully reasoned argument, which I regret could only be given in the merest outline here, will, I think, admit that we are entitled to supply as a missing corollary that the climate of our island, from its greater humidity and equability, provides even more effectively the atmospheric conditions required by the categories of patients to which he refers. It is arguable also that if immersion in mineral water has the influence claimed for it sea bathing must be even more potent, for the organic matter in sea-water renders it peculiarly adherent to the skin. One of the reasons for the increase in the number of Germans visiting the coasts of their own country and Belgium may be the perception of the fact that greater hydration of the skin is effected by the combined influence of sea air and sea water than by mineral-water baths, taken in the drier air of the German spas, even when assisted by inhalation of atomised salt solutions.

It is unnecessary for my present purpose to enter into a detailed discussion on thallasso-therapy, for I find the opinions recorded in French and German literature to be substantially in accordance with our own. But from the indication list of Thilenius, the most concise I have met with, I should like to subtract migraine and rheumatism, which I believe to be seldom indicated, and rickets, which can scarcely be considered a specific indication. I imagine, also, that most English authorities would agree in the addition to the list of convalescence from acute disease; while I think that we should lay stress on the special benefit derivable in our humid climate by patients suffering from the dry form of respiratory catarrh—a condition frequently met with in central Europe. The remaining indications given by the authority mentioned are: the scrofulous diathesis; tuberculous disease of bones, joints, and glands; predisposition to phthisis; emphysema of moderate degree; delicacy of the skin, and especially undue sensitiveness to cold; delayed development in childhood; and last, not least, neurasthenia from mental or physical overstrain.

The indication, predisposition to phthisis, calls for comment, since Dr. J. W. Gordon has drawn attention to the high ratio of phthisis morbidity in places exposed to strong prevalent rain-bearing winds. I suggest, therefore, that until this phenomenon is explained on other grounds we should caution our foreign colleagues against sending patients predisposed to the disease to the more exposed of our westerly stations.

Of the sea coast of Britain it is not too much to say that although it is impossible to point to any part which has not in summer an agreeable climate, yet climatic variety is its leading characteristic. Facing every point of the compass, some with scarcely any shelter from the wind, others well protected in land-locked bays, there are towns and villages presenting from June to September a graduated scale of invigorating climates not to be found on any other European seaboard and surpassed only by the antipodean island of New Zealand. There are, in addition, some adjacent inland stations where the climate under modified marine influence is remarkably well suited for patients who find the coast too stimulating.

The summer climate of our south coast from a point a little to the south of Margate on the east, to Penzance on the west, may roughly be compared with that of the French coast from St.-Pol-sur-Mer to Roscoff, or perhaps le Conquet, but local factors introduce so many modifications that there is little resemblance between the individual resorts. In winter, however, our best sheltered stations, from Bournemouth westward, owing to their southerly orientation, enjoy a milder climate than those of the French coast opposite. There is no maritime climate in France closely comparable with that of the east coast of Britain, from Margate to the north of Scotland, nor with the west coast, from Weston-super-Mare to the Hebrides. On the other hand, we have none in any way resembling that of the French coast from Arcachon to Hendaye, and still less that of the Côte d'Azur; but these regions, and especially the latter, scarcely come into the count as summer stations, at any rate for northern peoples.

Regarded from almost every other standpoint, the seaside resorts of the two countries lend themselves rather to contrast than comparison. For persons seeking the brightness and particular kind of gaiety of Trouville we have nothing to offer. They might as well ask for the Alps at Enghien or the Quartier Latin at Paramé. I do not know, moreover, in England of any little nooks of a type not uncommon in France, and well represented by Pourville. Places of that size are with us usually rough fishing hamlets, and hotels in any way equal to those in France are not to be found. For foreign invalids the most suitable of our seaside stations are those of moderate size. They are described by visitors who like them as dignified, well administered, and offering no form of excitement likely to distract attention from the pursuit of health; by those to whom they do not appeal, and who, of course, should never have been sent there, as insufferably dull. Eschewed in England by the "fast set," they attract the more sedate of the aristocracy and the steadier members of the professional and commercial classes, and so may well prove intolerable on the one hand, or congenial on the other, to corresponding sections of French society.

Between the long and indented coast line of Britain and the shorter and less varied German littoral not many comparisons can be drawn. Still, it is useful to remember that the mean summer temperature of the southern part of our east coast is about the same as that of the North Sea island of Borkum, while that of the northern portion finds its counterpart in the island of Keitum. These localities have other features nearly in common, the daily range of temperature on our east coast being only fractionally less and the hours of bright sunshine rather fewer, while the relative humidity is a little greater. I have not been able to procure the rainfall figures for all the stations, but between two that are sometimes compared I have found a rather surprising difference. In summer, when they come into rivalry, the rainfall of Margate, the most southerly of our east coast stations, is much less than that of Borkum; during the three summer months the mean rainfall for Margate being 112 mm. and for Borkum 212 mm.; while August, the driest month in the year at Margate, with 24·9 mm., is, at Borkum, the wettest, with 89 mm.

Of the Baltic resorts I have come across meteorological statistics only for Swinemünde, and it is interesting to note that the figures of mean summer temperature, and mean relative humidity, agree closely with those of Bournemouth.

In comparison with those of Germany, our coast towns have been longer resorted to for health and pleasure, and so have the advantages of age—with its disadvantages. Some of them are much larger, and the greater preponderance of a population permanently resident lends them a more sedate air. Laid out, originally, on no definite plan the minor streets are sometimes unduly narrow, and those towns which had their great rise during the worst period of English architecture are, it must be owned, frankly hideous. Thus is painted first the darkest side of the picture—the æsthetic. On the other hand, we can state as very solid advantages that their sanitation and water-supply are always unimpeachable, and that they are usually as neatly kept as the very best of continental spas. Along the sea front of the more important towns there are many miles of concreted walks, usually provided with rain-shelters, and also carriage roads of easy gradient. It is, indeed, the stereotyped repetition of a sea-front promenade, designed apparently to illustrate Euclid's definition of a line, that gives the British seaside town its distinctive *cachet*. It constitutes a feature of psychic as well as physical import, for not even the attraction of bands and minstrels can bring together, at the same time and in a limited area, a concourse of people sufficient to create a scene of animation such as we see in

foreign health resorts. At the hôtels, even when a *chef* presides, cookery is modified to suit insular taste, and the made dishes resemble somewhat those served at the *tables de régime* of continental spas.

More space than is taken up by the whole of this paper would be required for a study of the medical climatology of our east, west, and south coasts. That is a task which I hope to see attempted in the near future, and I would merely point out that whoever undertakes it, if he endeavours to view the subject through foreign glasses, will, necessarily, give some indications which would not hold true for English people. I have observed, when treating foreigners in London, that usually the sick-room temperature must be kept from one to three degrees Centigrade higher than would be tolerable to English patients. The explanation of this difference is, I suppose, that the winters on the Continent being longer and colder more efficient methods of domestic heating have been adopted, while the summers being uniformly warmer the body is exposed during the greater part of the year to a higher mean temperature. For that reason I believe that some of our winter stations will be found to be typically suitable in the height of summer for many continental invalids, the more delicate being directed to the south coast, though if delicacy is associated with a fair degree of physical activity the west coast should be given the preference. Thus the word "relaxing," hitherto dreaded as a death sentence, may prove a passport to renewed prosperity. When the foregoing principles come to be applied in practice, it will be found that foreign invalids may, with advantage to themselves, be sent to some of our stations just at the time when Britons are accustomed to desert them—a fortunate circumstance—for during the official season there is often little room for additional visitors.

The western section of the south coast would seem to me to be well adapted for patients suffering from simple catarrh of the air passages, after a course of intensive treatment at Ems or Mont-Dore. It would be on the safe side to represent the east coast as a summer playground for the fairly robust, or, using the word in a wide sense, as a "preventorium." Certainly there is no better preparation for the rigours of a winter in northern Europe than a month in autumn spent on almost any part of our east coast.

Since the coast line of Britain presents an almost continuous chain of summer health resorts, reasons might be offered for mentioning the greater number of them for the purpose indicated by the title of my paper, but even from a severely restricted selection I submit that the following, taken in geographical order, could not well be omitted: Cromer, Felixstowe, Margate, Hastings, Eastbourne, Ventnor, Bournemouth, Sidmouth, Torquay, and Tenby. Happy is the writer or speaker who is not called upon for full enumeration or to distinguish between the claims of so many famous places, for so fiercely burns the flame of local patriotism that whereas by commendation few friends are gained, by criticism a harvest of enmity is reaped.

I have left insufficient space for characterisation of the inland climatic stations—and you will readily forgive the omission. But if this communication should fall into the hands of any of our foreign colleagues I will ask them to accept the assurance that in Britain, from John o' Groat's to Land's End, it would be difficult to find an ugly district or one not typically healthy in summer; and that at the same season for the ideal of air, bracing yet not devoid of sedative qualities, there are few places in the world superior to Hindhead, Crowborough, Church Stretton, Ben Rhydding, and Okehampton in England; Braemar and countless others in Scotland. Strict regard for truth compels me to add that in these places amusements in the continental sense of the word are non-existent. No foreigner should go there who does not speak English well; he should take with him golf clubs and faithful friends.

In writing this short sketch I am well aware that I have but touched the fringe of a great subject. I shall be satisfied if by anything I have said the interest of foreigners is stimulated in our island as a health resort and summer playground, and still more if British physicians are induced, filling the wide gaps I have left, to present to the world in a fresh light the splendid climatic and mineral water stations of their own country.

Elvaston-place, S.W.

# THE USE OF IODINE AS A DISINFECTANT OF THE SKIN BEFORE OPERATIONS.

BY WILLMOTT EVANS, M.D., B.S., B.SC. LOND., F.R.C.S. ENG.,
SURGEON TO THE ROYAL FREE HOSPITAL.

WITHIN the last five years many articles have appeared in the medical journals on the value of iodine as an antiseptic in preparing the skin of the patient for operation, and sufficient time has now elapsed to enable those who have employed it to express decided opinions as to its value. The first advocate of its use in this country was Mr. H. F. Waterhouse, and with his conclusions as a whole probably all those who have used it will agree. But there are a few points in connexion with the use of iodine on which I should like to express my opinion.

I may say at the beginning that I think very highly of this method of sterilising the skin. It is simple and thorough; it causes less discomfort to the patient and has a less harmful effect on the skin; and when it is employed stitch abscess is decidedly less rare than when the ordinary antiseptic compress has been employed. The application of iodine is certainly liable to cause some irritation to the eyes and nose of those who apply it, though there are great individual differences in this respect. I should like to endorse what Mr. Waterhouse said in his article in THE LANCET[1]—namely, that the irritation to the surgeon and his assistants is much less if the iodine is dissolved in rectified spirit than if methylated spirit be the solvent employed. Chassevant used chloroform as a solvent, 30 parts of it dissolving 1 part of iodine, and I am inclined to think that this solvent would have some advantages. It is hardly necessary to say that it is essential that the part should not be washed before the iodine is employed, or if it is considered that washing is really necessary several hours should be allowed to elapse between the washing and the application of the iodine.

Mr. Waterhouse applies the iodine twice: first, two hours before the operation and then again immediately preceding the operation. I have thought it advisable to adopt this method in certain cases where the skin was in a very septic condition and many septic foci were present; but I have not found it necessary in the average "clean" operation, in which tissues are incised where no obvious sepsis is to be found, and I have been perfectly satisfied with the results. It is often, in my opinion, useful to wipe over the surface of the wound immediately after the operation, though if any lotion or even saline solution has been employed during the operation the iodine will have little penetrating power when subsequently applied.

The strength of the iodine solution requires, I think, a little further consideration; in some of my earlier cases I used a 4 per cent. solution, but it seemed to me that it had a very definitely harmful effect on the edges of the wound, and it exerted a slight retarding action on healing, and the same result was seen, though to a less extent, with a solution of iodine of the strength of the official tincture—namely, 2½ per cent. Later I used a solution weaker still—that is to say, half tincture strength, 1 in 80, or 1·25 per cent. I am sure this is amply strong for all ordinary cases.

A rather important question is how should the site of operation be shaved if iodine is to be used for the antiseptic. It is clear that ordinary soap cannot be used, otherwise the skin will be left in a condition exactly resembling that produced by washing, and the iodine solution will not be able to penetrate the epidermis. The use of solvent pastes which are much employed in America for removing the hair previous to operations is open to the same objection as ordinary soap and water, for the skin becomes sodden and will not permit the passage of the iodine. The method that seems to me to be the most convenient is to cut the hairs short with scissors and then to shave the part dry with a very sharp safety razor. By this means it is possible to get a very smooth surface without the use of any moisture. It is essential that the razor blade should be extremely sharp. It may be objected to this method that it is somewhat painful, but it need not be used until the patient is under the anæsthetic immediately before the iodine is

[1] THE LANCET, April 16th, 1910, p. 1063.

applied. Some surgeons have the part shaved several hours before the operation, so that there is time for the sodden condition of the epidermis to pass off before the application of the iodine, but this requires at least six hours or even 12 hours, and in this time some growth of hair will occur. Still, it is not a matter of much importance so long as an attempt is not made to apply iodine within a short time of shaving the part in the ordinary way.

Perhaps it is worth while to say a few words about colourless iodine. In all the various external applications of iodine attempts are often made to employ one of the "colourless iodines," and I only mention the point here in order to draw attention to the fact that colourless iodine has very little antiseptic power. Iodine is decolourised in several ways: by the use of any of the alkalies, by carbolic acid, by sodium thiosulphate, and by sodium sulphite, but in every one of these methods the iodine enters into combination, and thereby loses all or the greater part of the antiseptic power for which it is chiefly employed. For instance, if caustic potash is used potassium iodide and potassium iodate are formed and no free iodine is left, and it need hardly be said that neither the iodide nor the iodate of potassium has any great antiseptic power. Therefore, these "colourless iodines" are useless for sterilising the skin, and, in fact, they are of very little value for any purpose.

Harley-street, W.

# PULMONARY TUBERCULOSIS TREATED BY CONTINUOUS ANTISEPTIC INHALATION.

BY I. BURNEY YEO, M.D. LOND., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL; AND EMERITUS PROFESSOR OF MEDICINE IN KING'S COLLEGE, LONDON.

IN the issue of THE LANCET of Nov. 19th, 1910, p. 1505, in commenting on an interesting article by Dr. David B. Lees on the above subject published in that number, you remark: "It would be interesting to know whether other physicians obtain the same results." In compliance with this suggestion I venture to send you an account of my own observations made some years ago on this method of treatment. So long ago as August, 1876, I read a paper at the annual meeting of the British Medical Association at Sheffield, in which I called attention to the value of antiseptic inhalations in the treatment of phthisis. I was then on the staff of the Brompton Consumption Hospital. In that paper I mentioned the curious circumstance that Dr. J. Copland had reported the case of "a young man who had repeatedly come under his observation in an advanced stage of phthisis and had recovered completely his health after he had been for a considerable period employed in the manufacture of creasote." Here there must have been an approach to "continuous inhalation." That excellent observer, Dr. A. E. Sansom, had also testified to the "real value of the dry inhalation of carbolised acid in phthisis." To refer again to Dr. Copland, in his "Historical Sketch of the Treatment of Pulmonary Consumption," he observes: "The inhalation of the fumes of tar or of creasote, or of the terebinthinates very weakly diffused in the atmosphere breathed by the patient, is in some cases beneficial in impeding the advance of tuberculosis, or the formation of cavities, and in healing the surfaces of cavities which have been formed"

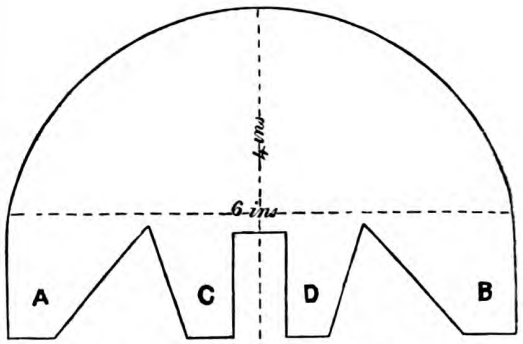
About that period Dr. (afterwards Sir) W. Roberts of Manchester described[1] a little respirator inhaler which he had devised for the inhalation of volatile antiseptics, and he testified that he had noticed benefit follow the use of these inhalants. He mentions cases of hæmoptysis in which the hæmorrhage ceased immediately on the use of inhalation of turpentine; also cases of phthisis with disease in both lungs and with very profuse purulent expectoration, in which the inhalation of creasote and iodine was of great apparent benefit; of laryngeal phthisis in which great relief followed the inhalation of equal parts of chloroform and olive oil. He had also found inhalations of the oil of eucalyptus of much value in relieving the cough and profuse expectoration in advanced phthisis.

[1] Brit. Med. Jour., Feb. 3rd, 1877.

In 1882 I again called attention to this subject in two clinical lectures I gave in King's College Hospital on "The Contagiousness of Pulmonary Consumption and its Antiseptic Treatment." These were subsequently published in a small volume which has been long out of print. Therefore, I may perhaps be permitted to quote from it here. After referring to Professor Jaccoud's treatise on the "Curability and Treatment of Pulmonary Phthisis," in which he testifies to the good effects of the internal use of creasote and the inhalation of a spray of carbolic acid, I describe a respirator inhaler for the continuous inhalation of antiseptic vapours which I had found to be extremely handy, light and convenient to wear, and very cheap. I described how they could be readily made.

You take a piece of paper about six inches long and four wide; you fold it along the middle, and cut it with a pair of scissors into this form. This is your pattern. (Fig. 1.) You place this on a piece of perforated

FIG. 1.



zinc, which costs about sixpence a square foot, and then, with a pair of stout scissors, you cut out a piece of zinc of the same size and form as the paper. By a little manipulation, for this zinc is very pliable, you can bring the two outer ends (A and B) together, so as to slightly overlap; and then, fixing them together with a twist of fine wire passed through the holes of the zinc, you get a suitable mouth-piece, or rather nose and mouth-piece, for it is important, I consider, to cover both nose and mouth. This can be bent to fit comfortably any face.

The two middle pieces (C, D,) now stick out behind, and, by gradually bending first one of these down, and then the other over it, you construct a little cage behind the mouth-piece which will hold a small bit of sponge, or a bit of tow or cotton-wool, or any suitable material for retaining the antiseptic vaporisable fluid. It is desirable to cover the rough edge of the mouth and nose-piece with some protecting material; a loop of elastic on each side serves to attach it behind the ears.

Messrs. Squire, of 413, Oxford-street, have now for many years made this little respirator inhaler, and in the form shown in the following figure (Fig. 2). This was immediately copied

FIG. 2.

The respirator in position.

in America in a slightly modified form by Messrs. Wyeth of Philadelphia, and it is described by Professor S. Solis Cohen in Hare's "System of Practical Therapeutics" as "one of the most useful as it is one of the simplest devices for the inspiration of medicinal vapours."

I go on to say that there are many antiseptic substances

the vapour of which may thus be continuously, or almost continuously, diffused into the air that is breathed.

Your choice may depend somewhat on the fancy of the patient, or you may change the applications, from time to time, until you find out in each case which is most useful.

Some simply keep the sponge moistened with carbolic acid, others prefer creasote, and others use spirits of turpentine. I have used all these alone as well as in combination. I have also used eucalyptol, thymol, terebene, oleum pini sylvestris, solution of tar in rectified spirit, tincture of benzoin, tincture of iodine, &c. Of all these I prefer creasote, but I also frequently use carbolic acid and eucalyptol. Turpentine is a useful addition as an astringent where there is profuse secretion or a tendency to hæmorrhage. I have also found it a very convenient plan to mix these substances, such as creasote, carbolic acid, eucalyptol, or turpentine, with equal parts of spirits of chloroform. It helps to diffuse and vaporise these substances and it is itself somewhat of an antiseptic, and it has also a soothing effect on the often irritable laryngeal and bronchial mucous membrane. A patient tormented with cough at night and unable to get any sound sleep will often obtain relief from this distressing symptom by using at bedtime one of these inhalations in an instrument of this kind. The quantity required for this purpose is often quite inconsiderable; it is rarely necessary to use more than twenty minims at a time of a mixture of equal parts of creasote and spirits of chloroform dropped on the sponge, and renewed occasionally as it becomes exhausted; and it is often desirable to begin with very small quantities, until the patient gets used to the vapour. One of the advantages of this little inhaler I have described is that, being perforated all over, the access of air is unimpeded, while the vapour diffuses itself freely into the immediately surrounding atmosphere.

I have adopted this plan of treatment in a number of cases, and in nearly all of them it has been attended with conspicuous benefit. Even in somewhat advanced cases it allays the cough, lessens the amount of expectoration, and diminishes the fever.

There is a young girl, 12 years of age, in the hospital now, an orphan with no obtainable family history, who was admitted three months ago in a wretched general condition, and apparently sinking from rapid phthisis. There was dulness all over the left side, with co-extensive moist crepitant and coarse râles; there was diminished resonance over the upper half on the right side, with diffused bronchial râles. The temperature was high and fluctuating, constant cough, much dyspnœa, loss of appetite, and great emaciation. She has been kept inhaling a mixture of equal parts of eucalyptol and spirits of chloroform; and, considering the miserable state in which she was on her admission, she has mended wonderfully. She coughs now very little, her appetite is good, she has gained flesh, and become quite cheerful. The moist sounds have completely disappeared from the right side, where the resonance is now good, and on the left side the catarrhal sounds have, to a great extent, disappeared, and the dulness is now limited to the upper lobe. She continues, however, to present a subfebrile fluctuating temperature.

I could enumerate a great many cases which have come under my care in which remarkable results have followed this method of treatment when it has been honestly and faithfully carried out. I wish to call your attention to the particulars of one such cure, in which, I must say, I have never seen better immediate results from this or from any other kind of treatment.

The patient was a married lady, 28 years of age, living in a low, damp locality, who had lost two brothers from consumption, one at 19 and the other at 23 years of age. She had had a cough for two years and had been losing flesh. She had been worse since her last confinement. Night sweats were constant, cough was troublesome, and expectoration abundant. Her voice began to be hoarse a fortnight ago, and was now nearly lost. Her appetite was bad. Pulse 112; respirations 20; temperature 101° F. She was considerably emaciated. There was some dulness over the left apex in front and behind, with moist clicks at the end of inspiration and some diffused largish crepitations on coughing. On the right side subcrepitant râles were heard over a spot just below the angle of the scapula, where there was also a patch of dulness. She was ordered to wear as constantly as possible one of my inhalation-respirators, charged with from 5 to 20 drops at a time of a mixture of equal parts of creasote and spirits of chloroform, so as to breathe an atmosphere only as strongly impregnated with the antiseptic as was quite comfortable to her. It was also agreed that she should remove to an isolated farm-house built on a hill 300 feet above the sea, between 30 and 40 miles from London, on the borders of Hampshire and Surrey, where there were pine woods and open heather country. She came to see me again after about three weeks, and she had improved immensely. The temperature had become normal; the night sweats entirely disappeared after a week of the treatment; her voice had returned after ten days; the cough and expectoration were greatly lessened. The dulness of the left apex was much less evident, but respiration there was feeble, and there was a distinct pleuritic creak in the left supraspinous fossa, a notable sign of past mischief in that region; all the moist sounds had disappeared. Her general condition had completely altered.

I had never seen a more striking improvement in so short a time under any plan of treatment or in any locality. But this patient had been unusually obedient to the instructions that had been given her. She had devoted herself at once and unhesitatingly to all the details of the treatment. She had removed immediately to an aseptic, if not an antiseptic, atmosphere; she had passed a great part of her time in a hammock suspended between fir-trees, in the situation I have mentioned, and she had perseveringly worn her inhaler as I had directed.

Dr. J. G. Sinclair Coghill, who was at that time physician to the Royal National Hospital for Consumption at Ventnor and had quite exceptional opportunities of testing this method of treatment of consumption, became a warm advocate of its adoption and devised a special respirator for the use of his patients, but it had the defect of only covering the mouth. He states that he had found "carbolic acid, creasote, and iodine, in combination with sulphuric ether and rectified spirits of wine, the most efficacious and satisfactory inhalant." In my "Manual of Medical Treatment" (Vol. II., Chap. IV.) I have given the names of many authorities who have testified in favour of this treatment, including Wilson Fox, McCall Anderson, Oertel, Solis Cohen, Dreschfeld, Semmola, Shingleton Smith, Mayo Robson, and others, and I have there given a detailed account of the method. I have been much gratified to see that it has now found so able and experienced an advocate as Dr. David B. Lees.

At one time, when I was on the staff of the Brompton Consumption Hospital, during which period more than 27,000 patients came under my care, I had very exceptional opportunities of applying and watching the various methods which had been advocated in the treatment of this widely spread malady; and I had formed, as I have said, a most favourable opinion of this method. But after the termination of my connexion with the Brompton Hospital these opportunities disappeared, and my studies in clinical therapeutics took and retained a more general character.

Cadogan-place, S.W.

## PERITHELIOMA (ANGIO-SARCOMA) OF THE GREAT OMENTUM; EXCISION.

BY W. GIFFORD NASH, F.R.C.S. ENG.,
SURGEON TO THE BEDFORD COUNTY HOSPITAL.

THE patient, a nurse, aged 43 years, on Jan. 1st, 1909, whilst lifting an old lady, felt something give way in her abdomen. On the 7th she came to see me complaining of pain and discomfort in the abdomen which had continued since the strain. She was a short stout woman, and examination of the abdomen showed nothing except some tenderness below and to the left of the umbilicus. I thought she had strained her left rectus muscle. On the 12th she had discomfort and flatulence. On the 16th I found the abdomen prominent, with evidence of a fluid swelling in the central portion. There was resonance in both flanks and along the transverse colon. The local condition suggested torsion of an ovarian cyst, with rapid increase of size. She was admitted to hospital on the 17th and next day the abdomen was opened in the middle line below the umbilicus. Eight pints of dark bloody fluid were evacuated. The pelvis contained several subperitoneal uterine fibroids, the largest of which was removed. Higher in the abdomen was found a soft fleshy mass which felt exactly like a placenta. This proved to be the great omentum, infiltrated with blood and oozing on the surface. There were no adhesions. The omentum was clamped in sections, ligatured with catgut, and removed from its attachment to the transverse colon. The stump left behind was thick and infiltrated with blood, and near the splenic flexure the peritoneum covering the colon presented an ecchymosed appearance. The wound was closed, and the patient quickly got over the effect of the operation. A week later a dose of castor oil was followed by hæmorrhage from the bowel. The stitches were removed on Jan. 27th, and on Feb. 4th the patient left her bed. On the 27th slight phlebitis occurred in the calf of the right leg, and on March 5th the same occurred in the left calf. On the 8th she complained of abdominal pain, and the recurrence of ascites led to a further operation on the 13th. The abdomen was opened above the umbilicus and a large quantity of blood-stained fluid was evacuated. The gastro-hepatic omentum was found to be in the same condition as that noticed in the great omentum at the previous operation. It could not be removed, and as blood was freely oozing the bleeding area was packed with gauze and the incision was partly closed. Death occurred on the 14th from continued hæmorrhage into the abdomen.

*Necropsy.*—At the post-mortem examination the abdominal cavity was found to contain a considerable amount of blood-stained fluid. There were numerous adhesions between the colon, liver, and stomach. The liver contained several nodules of growth scattered over its under surface. In the left lobe was a large growth. There were nodules on the descending colon, small intestine, diaphragm, right parietal pleura, and in both lungs. The gastro-hepatic omentum was

of a reddish colour and much thickened. The uterus contained numerous fibroids. The other organs were healthy.

The omentum removed at the first operation was exhibited at a meeting of the Obstetrical Section of the Royal Society of Medicine on March 11th, 1909, and referred to the Pathological Committee for examination. The report was that it contained a malignant growth of a peritheliomatous nature.

*Remarks.*—At the first operation I took the condition to be due to an accidental hæmorrhage into the great omentum caused by a strain. Acting under this impression, I showed the specimen at the before-mentioned meeting of the Obstetrical Section. No one present had seen anything like it, and it was not suggested that a malignant growth was present. It was, however, decided to submit the specimen to the Pathological Committee of the section. Before the committee met the patient underwent the second operation, and a post-mortem examination had revealed the secondary growths.

Primary sarcoma of the great omentum appears to be a very rare disease—in fact, text-books contain very little information on diseases and injuries of the omentum.

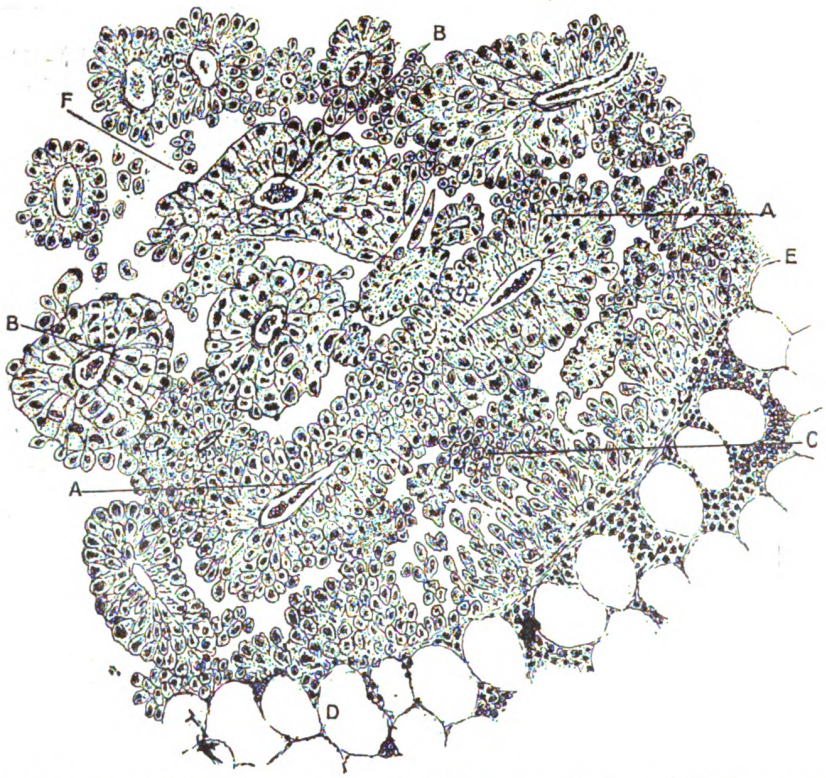
Dr. Farrar Cobb of Boston, Massachusetts, has reported a very similar case.[1] In his case the diagnosis was intestinal obstruction from malignant disease in the large intestine, presumably the sigmoid flexure. When the abdomen was opened bloody fluid gushed out, and a large, flat, spongy hæmorrhagic tumour presented itself in the wound. The incision was enlarged, and it became evident that the whole of the great omentum was much thickened and infiltrated with blood, its appearance being like that of a red bath sponge about one inch thick. A piece of omentum was excised, and nothing further was done. The patient lived for five weeks after the operation. The pathological report was: "A small piece of hæmorrhagic, necrotic-looking tissue, which was found to be composed of a solid mass of large round cells of varying size, among which were many mitotic figures. The blood-vessels were simply spaces hollowed out in the cellular growth. Large round-celled sarcoma." Dr. Cobb says:—

> The number of cases reported that have been accurately studied is very few, yet certain statements can be made as to the constant diagnostic symptoms and signs. There is no conclusive sign other than a palpable, flat, moveable tumour with or without signs of fluid in the abdominal cavity. From a study of the few similar cases reported, the symptoms and signs vary within wide limits, yet are mostly suggestive of chronic intestinal obstruction. In nearly all the onset of the disease was so slow that the tumour was felt as a flat or vaguely rounded mass before abdominal distension and constipation became extreme.
>
> In the majority of cases there is a long period of gastric symptoms, with malaise, loss of weight, vomiting, increasing constipation, alternating with diarrhœa and vague abdominal pain; then a tumour is felt in mid-abdomen, often a year or two before death. Fluid is then detected. In two cases bloody or dark stools are mentioned as having been seen.

When we consider my case, which was of the same nature as that recorded by Dr. Cobb, we must notice the absence of symptoms on which to found a diagnosis. There was dyspepsia for three months, then a distinct history of a strain which may have started bleeding from the omentum, already the seat of a malignant growth, followed by the comparatively early effusion into the peritoneum. No tumour could ever be felt through the thick abdominal wall. The patient did not lose flesh and was able to work until the day before the first operation. The condition of the omentum—soft, red, and oozing when touched, apparently infiltrated with blood—did not suggest a growth. This resemblance to a flat sponge full of blood I had never read of, and therefore did not recognise. The case ran an unusually rapid course, but the end was probably hastened by the operation, as relief of pressure allowed free oozing of blood from the growth.

The drawing of the microscopical appearance of the growth, for which I am extremely indebted to Dr. G. Harvey Goldsmith of Bedford, shows the typical radial arrangement of cells around the lumen of the blood-vessels. The omental fat is in places infiltrated with small round cells with darkly stained nuclei.

I can find very few references to perithelioma. Adami[2]



AA, Vessel cut longitudinally. BB, Vessel cut transversely. C, Closely packed masses of cells. D, Fat, infiltrated in places by darkly staining small round cells. E, Mesentery. F, Small isolated groups of cells.

[1] Annals of Surgery, 1906, vol. xliv., p. 16.

[2] Principles of Pathology, vol. i., p. 758.

says "that it is a striking form of tumour exhibiting capillary channels cut in various directions and lined by recognisable endothelium, around each of which capillaries is a collection of cells, many layers deep, arranged radially. The general opinion is that these cells gain their origin from the lymphoid endothelium of the perivascular space, that thus these tumours form one variety of lymphangio-endothelioma."

Bland-Sutton [3] has published an illustration of a case, and says that perithelioma is a sub-variety of the endotheliomata. Osler and McCrae [4] mention, amongst primary malignant tumours of the peritoneum, the occurrence of perithelioma (angio-sarcoma). They state that in some endotheliomata the microscopic appearances are confusing, in some parts resembling sarcoma and in others carcinoma.

Bedford.

## THE RELATION OF ACUTE PHOSPHORUS POISONING TO ACIDOSIS.

BY H. LETHEBY TIDY, M.A., M.B. OXON., M.R.C.P. LOND.,

MEDICAL REGISTRAR TO THE LONDON HOSPITAL; PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL.

IN this article I wish to emphasise the connexion of the secondary stage of acute phosphorus poisoning with acidosis. A distinction can be drawn between acidosis and acute acid intoxication, but this will not be discussed. The symptoms of acute phosphorus poisoning may be given briefly as follows:—

1. *Primary symptoms.*—Immediately on swallowing there is a disagreeable taste of garlic. Before the onset of symptoms there is a latent period with a duration of a quarter of an hour to upwards of two hours. Vomiting, with garlicky eructations, then commences. The vomit may be luminous. Purging usually occurs. There is no pyrexia. The usual symptoms of gastro-enteritis are present, and collapse and death may follow in a few hours from cardiac failure. If this rapid termination does not occur, the vomiting and purging subside, and about the third day the patient appears to be on the high road to recovery. There are cases on record in which the primary stage has been absent or very slight.

2. *Secondary symptoms.*—About the fourth day a fresh train of symptoms appear, the similarity of which to those of acute yellow atrophy of the liver has long been noticed. Vomiting is frequent. There is intense thirst. The pulse becomes small and feeble. Jaundice is early visible. In a short time the liver enlarges and is often extremely painful. This enlargement may, however, be absent. A tendency to hæmorrhage is present. The urine becomes scanty, and usually contains acetone and diacetic acid. Leucin and tyrosin may be present. There is great weakness, and delirium and loss of consciousness precede death, which in this stage is almost invariable.

*Post-mortem examination.*—When death occurs in the primary stage the stomach and intestines show signs of inflammation, and ulceration may be found. A peculiar smell is noticed and the contents of the stomach may be luminous, or even the whole body. No other changes are generally present which can be ascribed to phosphorus. No sign of phosphorus is usually found in the body on analysis when death has occurred more than three days after taking the poison. When death has occurred in the secondary stage all tissues of the body show extreme fatty degeneration. The liver shows changes similar to those found in acute yellow atrophy. It may, however, be enlarged. Leucin and tyrosin can be obtained from it. The stomach and intestines show but slight change beyond fatty degeneration. Hæmorrhages and petechiæ are common, as in all cases of advanced jaundice.

*Nature of the secondary symptoms.*—The primary symptoms may be ascribed to the irritant action of phosphorus and will not be further referred to. The secondary symptoms are not uncommonly stated to be a "recurrence" of the primary stage. The vomiting which occurs at the beginning of both stages may have established this view. The most prominent secondary symptoms are vomiting, epigastric pain, thirst, jaundice, and the presence of acetone and diacetic acid in the urine.

From a consideration of these in association with the post-mortem appearances the condition can be attributed to acidosis, of which the phosphorus is either the cause or the *causa causans*. It may be noted that diabetic coma is ushered in by epigastric pain, anorexia, and nausea. There is a marked similarity between delayed chloroform poisoning and the secondary stage of phosphorus poisoning. Thus there is a period of several days before the onset, and the symptoms and post-mortem appearances are similar. For these reasons one is justified in attributing the two conditions to a similar pathological state of the tissues, and we may classify together the second stage of phosphorus poisoning, acute yellow atrophy, delayed chloroform poisoning, the toxæmic vomiting of pregnancy, and other conditions undoubtedly associated with acidosis.

*The action of phosphorus.*—The toxic powers of phosphorus were formerly considered to be due to the withdrawal of oxygen from the tissues. The amount of oxygen necessary to oxidise a fatal dose is, however, very small, and this view is no longer held. The result of the process of oxidation is the important point. Phosphoric acid is very powerful and is nearly as strong as hydrochloric acid. The oxidation of phosphorus after absorption would result in the presence of this acid in the blood and tissues. Hutchison found that sodium di-hydrogen phosphate was the most powerful practical drug for acidifying the urine. I have been unable to find any instance of poisoning with phosphoric acid or symptoms resulting from an overdose.

*Treatment of the secondary stage of phosphorus poisoning.*—The measures employed in treatment of acidosis should be adopted. The injection of normal saline solution and the administration of alkalies should be commenced as soon as the vomiting and purging of the primary stage subside.

The presence of excess of acids in the tissues in the later stages of phosphorus poisoning has, of course, been previously noticed. Thus Meyer found the alkalinity of the blood to be diminished, and ascribed this to the excess of lactic acid in the body resulting from insufficient oxidation. Munzer in 1891 and 1892 examined the urine in ten cases of acute phosphorus poisoning, and found a high percentage of ammonia-nitrogen. In two cases he gave sodium bicarbonate and noted the reduction in this percentage, as must, of course, necessarily occur. The treatment was apparently tried for experimental purposes, in order to observe its effect on the excretion of ammonia. It was not persisted with, nor was it employed in a subsequent case. This was before much attention had been given to acidosis. Possibly other cases have been treated with alkalies, but I have not been able to find any record of such.

A close connexion between poisoning by phosphorus and arsenic is often assumed to exist. In acute arsenical poisoning there is no occurrence of a secondary stage, and post mortem no changes are found in the liver resembling acute yellow atrophy or phosphorus poisoning. There is no evidence that fatty degeneration occurs to any extent, except in the alimentary canal, in cases of uncomplicated poisoning with arsenic. Thus there is no reason to believe that acute arsenical poisoning has any relation to acidosis, and no evidence that chronic forms are connected with it.

## NOTE ON A CASE OF DIGITALIS HEART-BLOCK.

BY E. E. LASLETT, M.D. VICT., B.SC. LOND.

FROM experimental work it is well known that digitalis depresses conductivity in heart muscle. The demonstration of this effect in man is due to Mackenzie.[1] It is occasionally noticed that after digitalis has been administered for some days the pulse becomes irregular and shows intermissions. The intermissions have been shown to be due to the falling out of ventricular contractions owing to the failure of conduction of the stimulus from the auricle. Mackenzie states that this action of digitalis is obtained only when there is already some delay in conduction (which may be only slight) as shown by a lengthening of the *a.-c.* interval in the jugular venous pulse. This occurs particularly in subjects who have

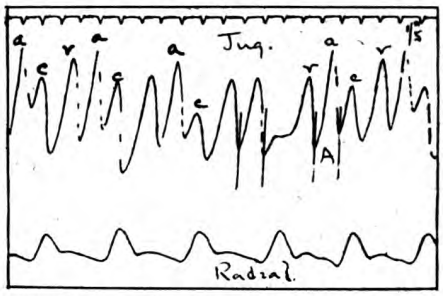
[1] Deutsche Medizinische Wochenshrift, 1904, No. 24.

had rheumatic fever. In patients with normal conductivity and intact *a.-v.* bundle digitalis remains without effect on the conductivity. This difference from experimental results is probably due to the fact that the amount of digitalis given to human beings is comparatively small, and its exhibition cannot be pushed beyond a certain stage by reason of its irritating effect on the alimentary canal.

It is not yet precisely known in what way digitalis acts on the function of conductivity in heart muscle, whether through the medium of the vagus nerve or directly on the muscle fibre itself. It undoubtedly produces one of its effects by its action on the inhibitory centre. It is in this way that it is able to diminish the frequency of the heart-beat. Mackenzie [2] reports a notable case of mitral stenosis in which digitalis, besides slowing the heart in the usual way, produced very long pauses—on one occasion for nearly four seconds—in which the whole heart was arrested. In this case, although there was damage to the *a.-v.* bundle and delayed conductivity, this was not further affected by the action of digitalis; in fact, the *a.-c.* interval was diminished after the long pauses.

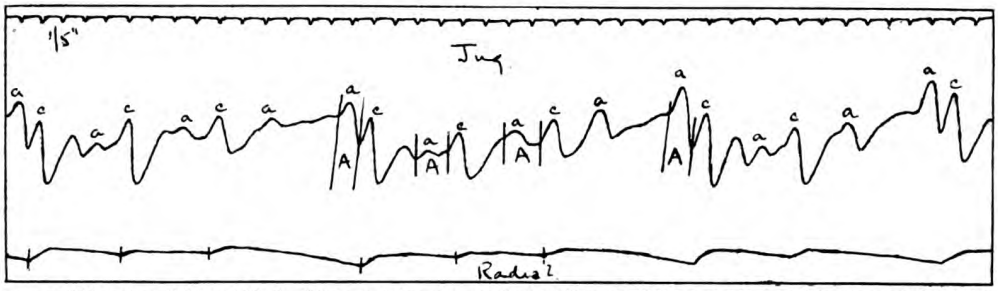
I have had under my care a patient in whom I produced partial heart-block by the administration of digitalin, and certain observations made during this period tend to show that in this case at least the heart-block was produced through the medium of the vagus nerve and not by direct action on the muscle. The patient was a woman, aged 40 years, who had mitral regurgitation as a result probably of an attack of rheumatic fever at the age of 20. The lesion appeared to be fairly well compensated, but there were attacks of violent palpitation. There was some degree of anæmia, and probably as a result partly of this and partly of the valvular lesion the field of cardiac response was somewhat limited. A jugular venous tracing taken in October, 1908, showed a large auricular wave indicating, perhaps, some loss of cardiac tone. The *a.-c.* interval at this time was slightly more than one-fifth of a second, with a pulse-rate of about 75 per minute (Fig. 1). There was thus a slight delay in conductivity. Digitalin granules were prescribed, one to be taken twice daily. No particular effect was noted until the eleventh day, when it was found that the pulse was intermittent, a beat being dropped after every second or third period, usually after every second. It will be seen from Fig. 2 that there is a gradual lengthening of the *a.-c.* interval until conduction fails altogether and a ventricular contraction falls out (Fig. 2). If now the patient swallowed once there were four normal pulse periods before an intermission occurred. If two or possibly three swallowing acts were performed in quick succession the intermissions temporarily disappeared. The pulse remained regular for nine periods of a slightly increased frequency (a rise from 75 to 82 per minute). Then two intermissions occurred in succession, and the previous rhythm was resumed. The appearance of two intermissions in succession (a 2 : 1 rhythm) was also noticed on several occasions after a single swallowing act. The venous tracing (Fig. 3) is somewhat marred by the muscular movements, but it shows fairly clearly that during the period of increased frequency caused by swallowing, conductivity is somewhat improved, as shown by the *a.-c.* interval, and that it is not until just at the end of the period that the interval lengthens and then the intermissions follow.

FIG. 1.



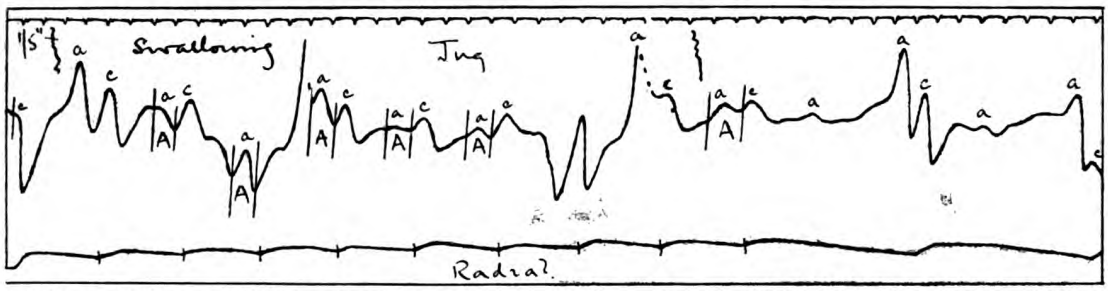
The normal venous pulse. The *a.-c.* interval is slightly more than one-fifth second.

FIG. 2.



Shows a condition of partial heart-block. The *a.-c.* interval gradually lengthens until it is equal to two-fifths of a second and then the ventricular contraction fails.

FIG. 3.



During swallowing, conductivity is somewhat improved, as shown by the *a.-c.* interval which does not lengthen until the end of the period of increased frequency.

Such a result seems to indicate that in depressing conductivity in the *a.-v.* bundle the digitalin is acting through the medium of the vagus nerve. It is well known that sipping quickens the heart beat, probably by a reflex diminution of vagal tone. Hence it would seem that the depression of conductivity, and consequent dropping out of ventricular contractions, is dependent upon increased vagus tone due to

[2] Diseases of the Heart (London, 1908), p. 342.

the action of digitalin. Indeed, if the action in this case were really on the muscle fibres themselves one would expect that an increased auricular rate would lead to an increased grade of heart-block because the conducting fibres would then have less time to recover than before. The occurrence of a temporary 2 : 1 rhythm after both a single and successive swallowing acts is of importance. It indicates a temporary depression of conductivity to a greater degree than before, and must be due to a subsequent increased vagal tone.

Mackenzie [3] has published the case of a man with mitral and tricuspid murmurs, in whom there was a depression of the function of conductivity. In this patient digitalin produced mild heart-block. A few days after the digitalin was withdrawn the pulse became regular, but swallowing caused ventricular silences after three normal beats. This condition continued for a week. Mackenzie believes that it arose through reflex stimulation of the vagus nerve, and from the analogy between the effects of digitalin and swallowing it indicates that the drug acts through the medium of the inhibitory centre and not directly on the heart muscle. I have tracings taken from an anæmic woman in whom I was able to produce partial heart-block by tincture of digitalis. In this case a day or two after the drug was withdrawn, and when the pulse had become regular, two or three swallowing acts performed in succession caused the pulse to intermit, but only after a temporary increase of rate. A single act of swallowing was inefficient. There was no history of rheumatism, and the peculiar sensitiveness of the heart to the action of digitalis may have been due to malnutrition. Since that time, although there has been little general improvement in the patient, I have never again been able to produce heart-block.

Hull.

## THE TECHNIQUE OF INTRAVENOUS INJECTION OF EHRLICH-HATA PREPARATION "606."

BY OTTO GRÜNBAUM, M.D. CANTAB., D.SC. LOND., F.R.C.P. LOND.,

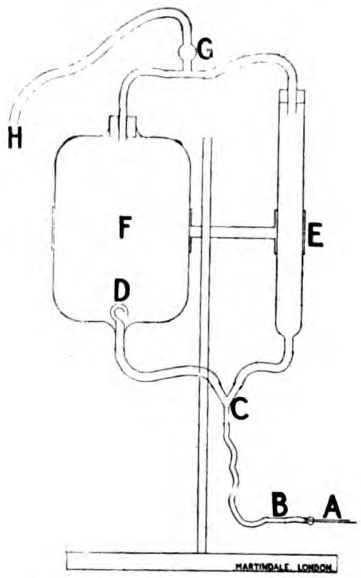
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL, ETC.

THROUGH the kindness of Professor Ehrlich I have been afforded opportunity of studying the effects of the preparation "606." My interest lies in diseases produced by the spirochæta pallida other than chancres and skin lesions, and it is chiefly to cases suffering from disease of the central nervous system that I have administered the drug. Professor Ehrlich's warning must be obeyed, and only very early cases treated. It is not my intention to take this opportunity of recording my results, but to give details of one of the methods of introducing the preparation into the body. My experience was similar to that of other observers, in that neurasthenic patients complained of pain for many weeks after the injection when this was made into the gluteal muscles. This was one of the reasons for my adopting intravenous administration of the drug which is painless.

The apparatus which I have used consists of a transfusion needle (A), connected by a short piece of rubber tubing to a piece of glass tubing (B), this in turn by a long piece of tubing to a three-way tube (C). An ordinary clip is placed between B and C. The other arms of the three-way tube are connected to the two vessels (E and F). F is of 400 c.c. capacity and should be calibrated. The outlet from the lower end of the vessel (F) should be similar to that in the diagram, in order that any small heavy particles, such as minute fragments of glass, cannot pass out of it. This, it is true, leads to the waste of a few cubic centimetres of the solution; in the apparatus I use this amounts to three cubic centimetres. E is a smaller narrower vessel. Clips are placed between C and F, and between C and E. The vessels are closed above by rubber corks, through which tubes pass to connect to the three-way tube (G). In G there is a filter of cotton-wool, and from it passes a tube connected to small hand-bellows. The object of this somewhat complicated apparatus is to permit of the injection of a small quantity of normal saline solution first, in order to be certain that the needle is in the vein.

[3] Brit. Med. Jour., 1906, vol. ii., p. 1110.

The details are as follows. The whole apparatus, including tubes, &c., is boiled. On removing it from the steriliser the vessels are corked and clips are placed upon the tubes, and the apparatus is kept until wanted. Hot normal saline solution is poured into the vessels. Clips C D and C E are removed, and the needle (A) is held as high up as the tubing will permit. Clip C B is removed, and the needle is



gradually lowered until saline solution runs through it; all the clips are then fixed. This ensures the tubes being emptied of air. In spite of this it is advisable to keep an eye on B during the injection, and to stop it should any bubble of air appear.

The solution is then prepared: the outside of a tube of "606" is sterilised after having notched it with a file. The contents are shaken into a sterile stoppered bottle of 60 c.c. capacity. If the contents of the tube appear to have formed into granules, and do not present the appearance of a fine yellow powder, it will probably prove to be useless for intravenous injection. The powder is dissolved in 20 c.c. of warm sterile distilled water. When solution is complete a half-normal solution of pure sodium hydrate is added drop by drop. A precipitate is thrown down, which dissolves on the addition of more sodium hydrate. However carefully the soda solution is added, the resulting solution is more alkaline than absolutely necessary. A sterile 10 per cent. solution of glacial acetic acid is added until a faint haze appears, and then a drop or two of a sterile tenth-normal solution of sodium hydrate until the solution is quite clear.

This solution is poured into the vessel F, in which there is not less than 250 c.c. of normal saline solution. All solutions should be made with distilled water; this, of course, applies to the normal saline solution. Occasionally on pouring the solution into the saline solution a cloudiness appears, which may disappear on the addition of a drop of the dilute sodium hydrate solution. If the precipitate persists the solution is useless and must not be used.

The skin of the patient in the region of the bend of the elbow is purified, and a bandage is passed once round the upper arm and twisted tight. When the veins are distended the needle is passed into one of them and the bandage removed immediately. Clips C E and B C are removed, and then the level of the fluid in E is seen to fall. If there be no swelling in the region of the point of the needle it is obvious that the needle is in the vein, and the injection of the drug may be proceeded with. Clip C E is fixed, and clip C D is removed. If the flow is too slow the air pressure in F may be slightly increased by compressing the hand bellows once or twice. When the vessel is almost empty clip C D is fixed, and clip C E is removed in order to wash out the vein with normal saline solution. The needle is removed, and the puncture is dressed with collodion and gauze.

The patient should remain quiet in bed for 24 hours.

During this time vomiting and diarrhœa may occur, but usually are of short duration. The patient is able to return to work 48 hours after the injection.

Portland-place, W.

## RAW MEAT AND RAW MEAT JUICE IN THE TREATMENT OF CONSUMPTIVE DISEASES (ZOMOTHERAPY).

BY J. HERICOURT, M.D.,

MEDICAL SUPERINTENDENT OF THE PARIS MUNICIPAL ANTI-TUBERCULOUS DISPENSARY AT JOUYE-TANIÈS.

IT is now some years since Professor Ch. Richet and the writer called attention to the remarkable effects of a diet of raw meat in enabling animals that had been inoculated with tubercle to resist infection, and in spite of the technical difficulties inherent in the administration of raw meat in any form to human beings the method has been tried and our conclusions confirmed by numerous observers; in fact, raw meat has become a recognised and important factor in the treatment of pulmonary and other forms of tuberculosis, as well as in anæmia, chlorosis, and similar states of *misère physiologique*.

As soon, however, as we endeavour to administer raw meat to human beings we are confronted with various difficulties, for the meat must be perfectly fresh or the pulp will be offensive, and the preparation of the pulp entails the expenditure of much time and trouble. Then, too, the amount that must be ingested in order to obtain the therapeutical effects is rather large, though satisfactory results have followed a minimum of half-a-pound a day. Lastly, many patients are unable, or at any rate unwilling, to take raw meat in any form, so that the treatment becomes inapplicable; moreover, the habitual ingestion of raw meat entails a certain liability to tænia, although, as a matter of fact, the risk is small, and if the worst comes to the worst the parasite is easily dislodged.

Subsequent researches, undertaken in conjunction with Professor Richet for the purpose of ascertaining which was the active constituent in muscle tissue, showed the specific elements to be contained exclusively in the muscle juice. We found, for example, that the solid components of flesh had no therapeutical action; indeed, tuberculised animals fed on flesh from which the muscle plasma had been expressed died in approximately the same lapse of time as the control animals, whereas the administration of the expressed juice to similarly tuberculised animals prevented infection taking place, for not only did they not fall ill, but they remained in particularly robust health, there being a substantial increase in weight after an interval of several weeks. Moreover, when the muscle juice was given to animals actually under the empire of tuberculous infection the emaciation ceased and they were restored to health, while the control animals died. It is obvious, therefore, that the efficacy of raw meat resides in the muscle serum—i.e., the meat juice—and it is equally clear that the effects are in no wise due to mere overfeeding because the proportion of nitrogen contained in 1000 grammes of muscle plasma only amounts to 4 grammes, roughly corresponding to 25 grammes of albuminoids. It follows that the recovery of dogs fed on a daily allowance of from 50 to 100 cubic centimetres of muscle juice could not be due to hyperalimentation, since by far the greater part of the nutritive principles remained in the expressed meat which proved unavailing in any quantity to prevent, or even delay, the fatal termination. To this method of treatment, based on the administration of raw meat juice as a remedial agent rather than as a food, we applied the name *zomotherapy*, from Ζωμός, meat juice.

Cooking destroys the organic principles to which the action of raw meat is due, and forced feeding with cooked meat has no action in delaying the course of the infection. This must be clearly borne in mind, because the various products described as "liquid meat," "meat juice," "meat extracts," &c., are all prepared from cooked meat, and, however valuable as foods, possess none of the therapeutical properties which we have shown to be inherent to raw meat.

A further advantage attending the use of raw meat juice is that it is free from the drawbacks which have been mentioned in connexion with the administration of the meat itself. The juice is easy to take and the amount to be ingested is comparatively small. Moreover, the taste is not unpleasant, is easily masked, and the risk of tænia is non-existent.

There remains, it is true, the technical difficulty of preparing raw meat juice economically and perfectly fresh. The first can be in great measure overcome by the employment of sufficiently powerful presses by means of which the proportion of expressed juice can be raised from 25 per cent. (which is the average yield with ordinary domestic presses) to 40 and even 50 per cent. There remains the difficulty of obtaining perfectly fresh meat, and this is one of the greatest importance, because meat juice is eminently unstable, so much so that its appearance changes within an hour of its separation, and it soon develops toxic properties which render it unfit for human consumption. To begin with, the juice must be expressed as soon as possible after the animal has been slaughtered—two or three hours in summer and four hours in winter. Then, too, the juice must be collected in a vessel surrounded by ice and consumed as soon as possible. No doubt these requirements make the treatment a troublesome one, and it is also somewhat expensive, but *qui veut la fin veut les moyens*, and its efficacy is such that it is very largely employed.

Our original researches were undertaken for the purpose of discovering a means of arresting tuberculosis, and the experimental and clinical results of the employment of *raw* meat and *raw* meat juice are as constant as they are remarkable. It is probably no exaggeration to say that the raw meat treatment of pulmonary phthisis yields results not approached by any other means at present available. Nevertheless, the benefits of zomotherapy are by no means limited to tuberculosis. Raw meat juice is of the greatest service in the various forms of anæmia and chlorosis, in typhoid fever, neurasthenia, rickets, and scurvy rickets, during convalescence, after hæmorrhage—in fact, whenever it is desired to reinforce the defensive apparatus of the organism and repair the ravages of disease.

There is, of course, no reason why the administration of raw meat pulp as a highly nutritious and digestible food should not be associated with the therapeutical employment of a muscle plasma; indeed, by adopting this plan we obtain the maximum advantages attending this method of treatment. It must, however, be borne in mind that to be efficacious the zomotherapeutic treatment entails the daily ingestion of at least the amount of muscle juice contained in 300 grammes of beef in mild cases and of 500 grammes and upwards in bad cases. Smaller quantities are no doubt productive of benefit, but cannot be relied upon to yield characteristic results. The inconclusive results reported here and there have been due to neglect of this cardinal principle, though it is only fair to add that one does meet with a few cases, usually those associated with secondary infections, which prove refractory.

The employment of raw meat juice for therapeutical purposes is based on purely empirical data, and we are not in a position to offer any scientific explanation of its action. At the time when we carried out our early experiments the theory of antitoxins had just been elaborated, and naturally enough the quasi-specific action of muscle plasma in tuberculosis was attributed to the presence of some antitoxic substance. Bearing on this hypothesis is the fact that tuberculosis never invades muscle fibre, and the well-marked muscular atrophy that occurs in phthisical subjects suggests the possibility of the muscles having been sacrificed in the defence of the organism. On the other hand, the presence in the raw juice of enzymes, ferments, and diastases which play such an important part in nutrition and in the struggle against infections may conceivably account for the activity of muscle plasma. It may be, of course, that muscle juice acts merely as a special stimulant of the nervous system. The slight but quite characteristic exhilaration that follows the ingestion of somewhat large amounts of muscle plasma militates in favour of the theory of nervous stimulation, and the good effects of zomotherapy in affections other than tuberculosis, neurasthenia, for instance, admits of a similar explanation.

Dr. Henry Percy Potter, medical superintendent of the Kensington Infirmary, has been presented by the staff with a silver coffee service on the completion of 30 years of office

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### NOTE ON A CASE OF MUMPS IN WHICH ATTACKS OF EPIDIDYMITIS OCCURRED ON EACH SIDE IN TURN, EACH ATTACK BEING ACCOMPANIED BY SYMPTOMS PROFOUNDLY INVOLVING THE NERVOUS SYSTEM.

BY SIDNEY PHILLIPS, M.D. LOND., F.R.C.P. LOND.,
SENIOR PHYSICIAN, ST. MARY'S HOSPITAL AND LONDON FEVER HOSPITAL; PHYSICIAN, LOCK HOSPITAL.

A MAN, aged 23 years, an army officer, was attacked by mumps in March, 1905. The left parotid gland was affected, and while the pain and swelling in it were subsiding the left epididymis became painful and enlarged. At the same time there was a rigor, the temperature rising to 104° F., and the patient became violently delirious, shouting and endeavouring to get out of bed. I saw him the next day; the delirium had passed off, but he had lapsed into a condition of deep stupor, seemingly quite deaf. He was not quite unconscious, showing signs of irritability when efforts were made to rouse him. There was retention of urine. His pulse was very rapid and small, his breathing laboured. The tongue and lips were very dry, and his breath was horribly fœtid. The skin was clammy; the extremities were cold; the temperature was 103°, but he seemed much collapsed.

The family were naturally alarmed, but remembering Trousseau's description of somewhat similar cases I was able to reassure his father—a medical man. The patient was given some calomel and a hypodermic injection of strychnine. On the next day he was better and he continued to improve. But five days later I was called again to see him for a recurrence of the symptoms. The right parotid had swelled up and his delirium, fever, and tendency to stupor had returned. I found that the right epididymis had now begun to be swelled and painful. After a few days all his symptoms lessened and he eventually got quite well.

*Remarks.*—Trousseau[1] narrates two cases illustrating the alarming symptoms which may accompany epididymitis following on mumps—one of a man, aged 35 years, who with the onset of the epididymitis became alarmingly ill, "with a countenance of inexpressible anxiety, face pale and pinched, pulse small, rapid, and irregular, and extremities cold"; the second case was that of a youth, aged 17 years, who was seized with acute symptoms "resembling those of the bad days in the third week of putrid fever." Trousseau also alludes to cases previously recorded by Boisieri.

My friend Mr. Mitchell showed me his notes of his case, and I have thought the record of my case might be of interest side by side with his. They both exemplify the very severe nervous disturbances which may arise with epididymitis after mumps. In his case an additional point of interest was the occurrence of epididymitis in an undescended testis; and in my case there was noteworthy: (1) the involvement of each epididymis in turn, on the same side as the parotid was affected; and (2) the separate attacks of delirium and stupor concurrently with each attack of epididymitis.

Upper Brook-street, W.

### A CASE OF ACUTE ORCHITIS OCCURRING IN AN UNDESCENDED TESTIS AFTER AN ATTACK OF EPIDEMIC PAROTITIS, AND ASSOCIATED WITH ACUTE DELIRIUM.

BY W. S. MITCHELL, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE ACTING GOVERNMENT MEDICAL OFFICER, GRENADA, B.W.I.

WHILE acting as medical officer of No. 2 District in Grenada, British West Indies, I was called up one night to sign up a patient who was supposed to have gone mad. The patient, a negro labourer, aged about 33 years, was in an acutely maniacal condition. He was lying in bed, restrained by three powerful men. I had the greatest difficulty in approaching him, as he bit, fought, and spat at me in a most terrifying manner. The only history I could obtain from his friends was that he had been in that condition for three days, previous to which he was apparently quite well, except for an "attack of the mumps" the week before, and that he had a "little fever." He had followed his usual occupation, which was of an extremely arduous nature. He had vomited once the previous day, and his bowels were "fairly regular," but he was dirty in his habits. He declined to take any nourishment. I found it impossible to approach him for some time, and owing to his extreme violence the hovel was in great danger of collapsing upon us, as it began to sway to and fro in a most ominous and threatening manner. After about an hour he quieted down a little, and I found his pulse was rapid but regular, and of moderate tension. The temperature in the axilla was 104° F. The lips were tremulous and dry, the eyes were bright and staring, and the pupils were dilated but reacting to light. The patient would not speak or put out his tongue. The heart was dilated and the lungs were normal. The abdomen was flat. The spleen was not enlarged. The left rectus was rigid and some tenderness was present on pressure below and to the left of the umbilicus. The right rectus was quite flaccid. Nothing could be felt in the left inguinal canal, but the patient resented this examination most forcibly, whereas he did not object to the right canal being examined. There was no discharge from the penis. On examination of the scrotum I found that the left testicle was undescended and could not be felt; the right was present and normal. The latter part of the examination was carried out under great difficulty, owing to the pugilistic efforts of the patient.

Morphia (½ grain) was administered hypodermically, and this quietened the patient, so that it was found possible to get him to take a little milk, in which was a powder consisting of calomel, gr. v., and pulv. jalap co., ℥ss. Hot poultices were ordered to the abdomen. On my visit the next day the patient was very much better, and no longer needed restraining. He told me he had some pain in the lower part of his abdomen, and that his memory was "not too good," but otherwise he felt fairly well. His temperature was 100°, the pulse 110, and his tongue was dry and furred. The left rectus was less rigid, but there was still tenderness on examination of the left canal. The patient could give no history of any injury. The hot poultices were continued, and a quinine mixture was ordered. His diet consisted of milk and eggs. On the fourth day I found the patient walking about in front of his hut, apparently in the best of health, and he informed me he intended turning out to work on the following day. I subsequently made inquiries and was told that he did go out to work, and that he had since enjoyed good health.

*Remarks.*—There are several points of interest in this case. The occurrence of orchitis in mumps is a well-recognised complication, but for the condition to occur in an undescended testicle must be almost unique. It will be noted that there was an interval of about a week between the parotid affection and the testicular complaint; this is in accordance with the usual sequence of events when the testis is affected. This interval rendered the diagnosis less obvious in the case under consideration. The fever, severe pain, rigidity of the left side of the abdomen, and vomiting might readily have led to the diagnosis of some acute inflammatory affection of the abdomen if the position of the testis and the history of the illness had not been taken into consideration. This rare condition must therefore be added to the list of affections requiring differential diagnosis in cases presenting acute abdominal symptoms. The occurrence of delirium in mumps is an occasional happening, but acute mania following the disease must be excessively rare. As far as the writer knows only one case has previously been recorded (that is, the one referred to in Osler and Macrae's "System of Medicine"). The swelling and pain in the testicle when affected in mumps usually last four or five days. In this case the patient was quite well within a week from the onset of the acute symptoms.

Grenada, British West Indies.

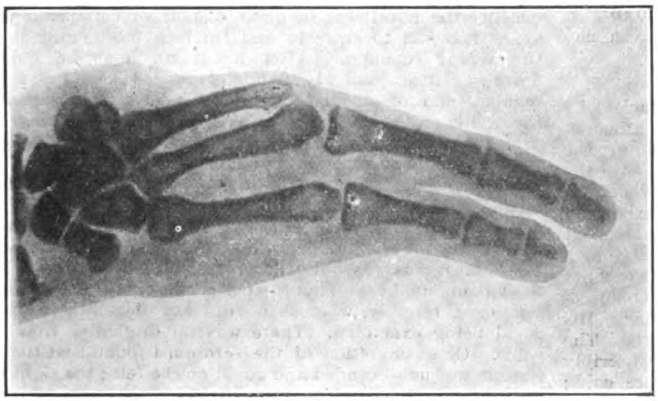
## CLOVEN FEET AND HANDS.

BY JOHN BELL, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H., SUPERINTENDENT, GOVERNMENT CIVIL HOSPITAL, HONG-KONG.

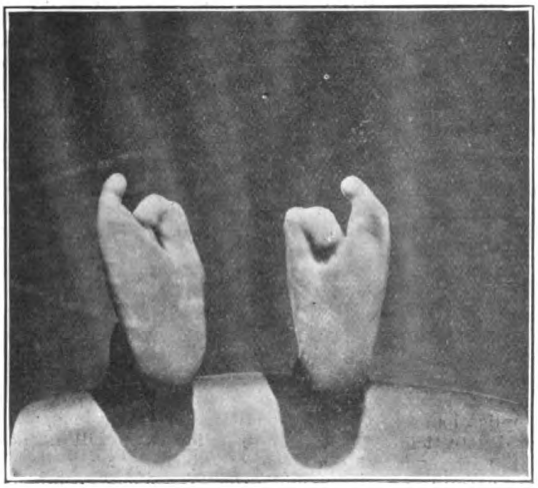
THE accompanying pictures illustrate what I believe to be a rare congenital malformation, and they may therefore be of interest. The subject was a Chinaman, aged 26, who was sent to us at the Civil Hospital, Hong-Kong, as a curiosity. Except for his hands and feet he was normal in all ways,

FIG. 1.



Reproduction of skiagram of right hand; the skiagram of the left hand showed similar deformity.

FIG. 2.



Reproduction of photograph of feet, the hooked halluces bein very marked.

and, indeed, a good specimen of his class. No family history as to similar or other deformities could be obtained. He was able to use his chopsticks between his fingers in a most dexterous manner.

Hong-Kong.

## THE TREATMENT OF BASIC MENINGITIS BY THE INUNCTION OF IODOFORM OINTMENT.

BY HAROLD MOWAT, M.D. EDIN.

I WAS interested in reading up the subject of meningitis to find a reference in THE LANCET of Sept. 30th, 1905, by Mr. H. C. Wilson to the value of inunction of iodoform ointment into the neck in a case of tubercular meningitis. The writer claimed that he had treated a case of this deadly disease successfully by this means, and, while admitting that the diagnosis of "tubercular" might possibly be incorrect, stated that all the symptoms of the case pointed to such an origin. It occurred to me that it would be useful to try the inunction in cases of ordinary basic meningitis of the toxæmic variety, as our ordinary remedies have never proved very efficacious, the mortality from the disease being extremely high. Within the last few months I have been successful in two cases, and believe that the satisfactory results were largely due to the inunction.

The first case was that of a boy, aged 9 years, who contracted measles. When the rash had disappeared a temperature of 103° F. remained, and the boy complained of severe frontal headache and stiffness of the neck. His neighbours were kept awake during the night by his shrieks, which were of the typical meningeal type. These passed off in two days and were replaced by constant moaning. He took no notice of his surroundings, except when sharply spoken to, when he replied to questions in a dazed fashion. He was very sick. *Tache cérébrale* was well marked, the muscles of the neck were rigid, while Kernig's sign was also present. As soon as I was told of the screaming I suspected the onset of meningitis and made up an ointment containing 15 grains of iodoform to the ounce of vaseline, which I instructed the parents to rub thoroughly into the back of his neck and posterior part of his scalp night and morning. I also gave him small doses of potassium iodide and bromide. Within the week his symptoms were greatly relieved and his temperature had fallen. Since then he has been in perfectly normal health.

The second case was that of a girl 3 years old, whom I treated quite recently. She was taken ill with severe diarrhœa and vomiting, attributable to the eating of a sausage on the previous day. Under treatment the diarrhœa soon disappeared but the sickness continued. She uttered the meningeal cry and afterwards moaned. She took no notice of anyone except when she was spoken to. Her temperature rose to 102° F. Her tongue was clean. *Tache cérébrale* was present. Kernig's sign was apparent on the fourth day. She squinted and showed marked extensor reflex of the big toes. On the sixth day she sank into a comatose state. I treated her in the same manner as the former case, but when the state of coma was reached I was compelled to tell her parents that I considered the case hopeless. On the eighth day she woke as from a natural sleep, spoke to her parents, and showed every sign of recovery. Since then she has had no relapse. Although I told her mother to apply the iodoform ointment twice a day she afterwards informed me that she had done so four times within each 24 hours.

Personally I have now a good deal of confidence in this method of treatment, and believe if it were more largely used our mortality from meningitis would be lessened.

Bromley-road, S.E.

## A CASE OF FISTULA OF THE LACRYMAL SAC.

BY S. CHURCHILL, M.A., M.B., B.C. CANTAB., HOUSE SURGEON TO THE ROYAL ISLE OF WIGHT COUNTY HOSPITAL, RYDE; LATE HOUSE PHYSICIAN TO ST. THOMAS'S HOSPITAL, LONDON.

THE accompanying illustration shows a unilateral fistulous opening whereby the right lacrymal sac communicates with the exterior by a channel other than those afforded by the canaliculi and the naso-lacrymal canal.

The patient is a married woman, aged 26 years, who was sent to the ophthalmic department as a case of lacrymal obstruction. Mr. H. J. May examined her. He was unable to squeeze any mucus or pus from the sac through either punctum and asked me to confirm this by syringing the canaliculi. This I did and noticed that the fluid issued as a jet from the region of the lacrymal sac. At first I thought this was due to the presence of obstruction causing the fluid to return through the upper punctum. But on closer examination I found a minute opening in the skin over the lacrymal sac, skirted by a semilunar fold and admitting the point of a Nettleship's canaliculus dilator. A piece of

horse-hair pushed into the opening (as in illustration) passed for a length of 3 inches down into the nose. Fluid injected by either the upper or the lower canaliculus is partly voided from the nose and throat and partly from this opening.

Referring to J. H. Parsons's "Pathology of the Eye," vol. iii., Part I., p. 906, the following words on the subject of fistulæ occur: "They have been attributed to arrest of

development, and minimal failure of the fissura facialis to close (Harman). This may be true of some cases, but they are probably more often of inflammatory origin. There is usually blennorrhœa of the sac. Adler attributes the fistula to arrested development and the blennorrhœa to fœtal inflammation, an unnecessary complication." As there is no evidence in this case of blennorrhœa, I conclude that this is a presentation of the morphological variety.

Ryde.

# Medical Societies.

## UNITED SERVICES MEDICAL SOCIETY.

*The Development of the Army Medical Service.—Pruritus Ani.*

A MEETING of this society was held at the Royal Army Medical College on Dec. 14th, 1910, Surgeon-General W. BABTIE, V.C., C.M.G., being in the chair.

Lieutenant-Colonel M. W. H. RUSSELL, R.A.M.C., opened a discussion on Recent Tendencies in the Development of Army Medical Services. He pointed out that under modern conditions it had become impossible for wounded men to be removed from the fighting line till dark, or at any rate till there was a lull in the fire; the wounded at the front could only be collected in "nests" and treated by the regimental *personnel* till this happened, and so there was a general tendency in most armies to increase the efficiency of the regimental aid by improving training and increasing the regimental supply of appliances. He suggested that in our army the water *personnel* should be made available for regimental aid during action, since their duties in connexion with water were in abeyance at that time; also that we might well follow the example of Germany, France, and Austria in making the regimental bearers devote their whole time to their bearer duties, and thus become not only more efficient but entitled to the protection of the Geneva Cross. The speaker then discussed the uses and organisation of collecting stations for lightly wounded, which are established five or six miles behind the firing line, and which occupy themselves not only in attention to lightly wounded men, so relieving the dressing stations, but also in the care of those unfit to go into action and in the collection of improvised transport. Lastly, he drew attention to the very considerable changes in arrangements which were likely to follow the more extended use of mechanical transport in war.—Lieutenant-Colonel C. H. BURTCHAELL, R.A.M.C., thought it would be impossible to combine the duties of water men and first aid. He also thought it impracticable to send lightly wounded direct from the regiments to the collecting station; in the Japanese army these men passed through the dressing station.—Major C. F. WANHILL, R.A.M.C., protested against the diversion of water men from their legitimate duties.—Colonel A. PETERKIN, A.M.S., doubted if one collecting station for a division would be sufficient on account of the distance from the flanks.—Surgeon-General BABTIE called special attention to the alterations necessitated by the employment of mechanical transport.—Surgeon-General G. J. H. EVATT, A.M.S. (retired), Lieutenant-Colonel A. P. BLENKINSOP, R.A.M.C., and Lieutenant-Colonel H. D. ROWAN, R.A.M.C., also took part in the discussion.—Lieutenant-Colonel RUSSELL, in reply, pointed out that in action everything, even sanitation, must be subordinated to the defeat of the enemy, hence his recommendation to utilise the water men for first aid at this time. As the collecting station was five or six miles in the rear there was no need to duplicate these establishments.

Major W. E. MILES, R.A.M.C., T.F., read a paper on Pruritus Ani. He was of opinion that it should more properly be labelled "dermatitis ani." He considered that it was not of nerve origin since most cases yielded to local treatment, but that it usually arose in patients with a gouty or eczematous diathesis, and that of the exciting causes rectal constipation was the most prominent. Treatment consisted in local applications of hot water, sedative and astringent ointments and powders, and in the removal of the exciting cause, especially rectal constipation.

Major T. W. GIBBARD, R.A.M.C., showed a case of Extensive Syphilitic Ulceration of the Head and Face which had resisted the usual treatment but which healed promptly after injection of "606." The demonstration was accompanied by photographs of the condition before and after treatment.

## LIVERPOOL MEDICAL INSTITUTION.

*Miscellaneous Business.—Operations for Varicose Veins.—Ehrlich-Hata Remedy for Syphilis.*

A MEETING of this institution was held on Dec. 22nd, 1910, Dr. T. R. BRADSHAW, the President, being in the chair.

In reply to a communication from the Education Committee addressed to the secretary the following resolution was passed:—

The members of the Liverpool Medical Institution are absolutely opposed to any plan by which school children found on inspection by the school medical officer to be defective receive treatment by the voluntary hospitals. They are also of opinion that the fee proposed by the local education authority for the correction of defective vision is inadequate.

Mr. R. E. KELLY read a note on the Operations for Varicose Veins. He gave an account of the historical evolution of the various methods of operative treatment and then described Mayo's operation, which he had performed recently about 12 times with excellent results.—Mr. K. W. MONSARRAT read a note on the same subject. He considered that no standard operation was suitable to all cases; that as reflux from deep to superficial veins was the main cause of varicosity in the latter, it was of the first importance to ascertain where this reflux was occurring. On this investigation depended the choice of operation. There were three types of operation: (1) simple resection of the internal saphenous close to its termination; (2) resection confined to varicose branches below the knee; and (3) total saphenectomy.—Mr. W. THELWALL THOMAS, Mr. RUSHTON PARKER, and Mr. G. P. NEWBOLT all considered that there were some cases which no operation would cure.—Mr. THOMAS said that usually some modification of the Trendelenburg operation was the best. In Trendelenburg's original description the saphena was ligatured at the junction of the middle and lower third of the thigh or a little lower. Mr. Thomas found that this was not always satisfactory, and in 1896 recommended in the *Liverpool Medico-Chirurgical Journal* that the vein should be tied near to the saphena opening.—Mr. NEWBOLT mentioned the case of a patient in whom the operation promised to be very

successful, and was so for four years, but after that time the varicosities returned in greater degree than ever.

Dr. R. STOPFORD TAYLOR and Dr. R. W. MACKENNA communicated a paper on the Ehrlich-Hata Remedy for Syphilis. They pointed out that the last five years had been full of great advances in their knowledge of syphilis, and referred to the work of Schaudinn, Neisser, Metchnikoff, and Wassermann. They then described the history of the use of the arsenical derivatives in the treatment of syphilis—Donovan's solution, atoxyl, arsacetin, hectine, and arsenophenylglycin, "418." Three years ago Ehrlich pointed out that the arsenic in atoxyl was fixed, not to the amidogen group, but to the benzine nucleus. This was the first step which led to the discovery of "606." The chemical formula of "606" was described, and the great danger of oxidation unless the preparation was mixed immediately before use was mentioned. Dr. Taylor and Dr. MacKenna recommended the method of Michaelis for preparing the powder, but considered that the intravenous injection was incomparably superior to intramuscular injection. They detailed the effects of the remedy on some syphilitic lesions and these were extraordinary. The primary sore became smaller in 48 hours, and the secondary symptoms disappeared in about a week. Mucous patches in the throat disappeared in 36 to 48 hours. Tertiary ulcers of the pharynx and periosteal nodes lost their painfulness in 24 hours after one full dose. The remedy acted by a powerful lethal effect upon the spirochæta, the protoplasm of which contained chemo-receptors which had a special affinity for "606," and also by the liberation of endotoxins from the spirochætes thus destroyed, which brought about the production of antibodies. That antibodies played a part was shown by the fact that syphilitic babies nursed by their mothers got well, but no arsenic was found in the milk. The dangers of the administration were pointed out, but when Ehrlich's directions were followed the mortality had been only 1 in 1000. Optic atrophy had occurred in only 1 out of between 20,000 and 30,000 cases. The remedy might be of use in pachymeningitis and gummatous infiltration. A number of cases treated by Dr. Taylor and Dr. MacKenna, including some under the care of Mr. Arthur Evans, were then referred to. The most remarkable was that of a man, aged 30 years, who developed syphilis in April, 1910. When seen he had numerous mucous patches on the tonsils and soft palate with glandular enlargement and pain on swallowing. He received an injection of 0·6 gramme intravenously. Within 24 hours he could swallow without pain, and in 48 hours the mucous patches had completely disappeared. Another case was that of a man, aged 25 years, with a chancre on the lip and a macular rash, who received 0·45 gramme intramuscularly. In one week both the rash and the chancre had disappeared. Dr. Taylor and Dr. MacKenna concluded with a tribute to the genius of Ehrlich, and expressed the opinion that in the new remedy they had a unique weapon against syphilis.—Mr. ARTHUR J. EVANS then gave details of seven further cases in which he had used the remedy, the result in each case being the rapid disappearance of the signs of the disease. Constitutional symptoms were often marked but transitory.—Several questions were asked and these were replied to.

## LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

*Exhibition of Cases.*

THE first clinical meeting of the session was held on Dec. 16th, 1910, Dr. J. DOBSON being in the chair.

Mr. A. L. WHITEHEAD showed a case of Wound of the Eye, Frontal Sinus, and Cerebrum, caused by a pellet from an air-gun. The eyeball was ruptured and was therefore excised; the fragments of bone splinters were removed from the frontal sinus and the roof of the orbit. A skiagram showed that the pellet had broken into two pieces; one was removed, but the other could not be found. Subsequently an attempt was made to remove this portion, using the X ray screen, but without success, the bullet still remaining in the frontal portion of the cerebrum.

Mr. H. SECKER WALKER showed a case of Electric Cataract caused by severe burning of the face by electricity (3000 volts). Several plastic operations had been done for the relief of the deformity produced by cicatrisation.

Dr. A. G. BARRS showed a woman, aged 26 years, who had suffered from Cerebral Tumour with two years' history of symptoms—headache, vomiting, optic neuritis, and convulsive attacks. Three weeks prior to the operation sight had suddenly failed almost completely. On Oct. 26th a decompression operation was performed; a trephine hole two inches in diameter was made beneath the left temporal muscle; the dura mater was not opened. By Nov. 21st headaches and vomiting and fits had entirely ceased. There was great improvement in vision and the optic neuritis was clearing up. Power of walking, which had been lost, considerably returned. On Dec. 16th improvement was still maintained.

Mr. B. G. A. MOYNIHAN showed a case in which Transgastric Resection of an Ulcer on the posterior wall of the stomach had been performed. The patient, a female, aged 51 years, had suffered from "indigestion" since the age of 16. Pain came on within half to one hour of taking food, and was always worse on the left side along the costal margin and up to the breast; vomiting relieved the pain. An operation was performed on Nov. 18th last. A large ulcer was found on the anterior surface of the stomach, adherent to the anterior abdominal wall. On the posterior surface of the stomach there was a large ulcer adherent to the tail of the pancreas. The anterior ulcer was excised, and through the opening so made the posterior ulcer was excised and the cavity in the pancreas closed by suture.

Mr. WALTER THOMPSON showed: 1. A case of Trigeminal Neuralgia treated by injection of alcohol in a patient aged 62 years. The neuralgia was of four years' duration, following extraction of a left upper molar tooth. Pain was increasing and was paroxysmal in character. The patient had been operated upon on Sept. 19th, under cocaine, alcohol (80 per cent.) being injected into the nerve at the foramen ovale and the infra-orbital foramen. Considerable improvement had resulted. 2. A case in which Hernia of the Small Intestine had occurred into the lesser peritoneal sac. In 1909 gastro-enterostomy was done at another hospital. On April 25th, 1910, the abdomen was opened because of persistent vomiting. A considerable amount of the small intestine had passed through an opening in the posterior layer of transverse mesocolon; the opening would admit the hand. The intestine was reduced, and the margin of the opening stitched to the line of gastro-enterostomy junction. On Sept. 22nd symptoms recurred, and the abdomen was again opened. The upper foot of jejunum was found adherent, kinked, and obstructed. The adhesions were freed and lateral anastomosis was done.

Dr. A. BRONNER showed a case of Glaucoma treated by trephining the sclera at the corneal margin, and by cyclodialysis (Fergus's operation). In this case a previous iridectomy and posterior sclerotomy had failed to relieve the tension, which was now considerably improved.

Dr. E. F. TREVELYAN exhibited: 1. A case of Stationary Muscular Atrophy limited to the hands. The patient, a female aged 24 years, showed considerable wasting and corresponding paralysis of the small hand muscles. Nutrition and power of the forearms and arms were perfect. There were numbness and diminished knee-jerk in the left leg. The present state was the same as when the patient was shown to the society six years ago. 2. A woman aged 32 years with marked habit spasm affecting the head. Improvement had taken place under electrical and exercise treatment.

Mr. J. F. DOBSON showed a boy, aged 19 years, who had sustained a Fractured Base with Cerebral Compression for which an intermusculo-temporal decompression operation was performed. He was admitted into the infirmary on May 2nd, 1910, having fallen from a ladder. Symptoms of fracture of the base of the skull were present, with very severe cerebral compression. At the operation a fracture of the vault running down into the base of the skull was found, with extra-dural and intra-dural hæmorrhage. Removal of clots and drainage of the subdural space were performed. Cerebral irritation was present for some days after the operation. The patient still complained of some headache and dizziness.

Dr. W. H. MAXWELL TELLING showed: 1. A man who had had an Acute Arthritis of one joint from oral sepsis. He was first seen on August 31st, 1910, and then had marked swelling of the right wrist-joint of five weeks' duration, with

much œdema, pain, and thickening affecting the right wrist and carpus. There was no gonorrhœa or previous joint affection. The mouth, which was full of carious stumps and in a very septic condition, was treated antiseptically. Guaiacol carbonate was given internally and the teeth were extracted, with immediate and rapid improvement of the joint condition. By Nov. 9th, all acute inflammation disappeared, only a little stiffness of the joint remaining. 2. A woman, aged 39 years, who had had Pernicious Anæmia of the severest type and who had made a marked recovery. She was admitted into the infirmary on August 6th, 1910, with a history of pernicious anæmia of four years' standing, with relapses. On admission the attack had lasted 14 weeks, and she was extremely ill, being jaundiced, very anæmic, vomiting almost all food, and having retinal hæmorrhages and dilated heart. Blood showed the changes typical of pernicious anæmia. August 8th: Red cells, 1,112,500; hæmoglobin, 40 per cent.; colour index, 2. The patient was treated with arsenic and cacodylate of soda but got worse, and her case was regarded as hopeless. Sept. 15th: It seemed impossible that she could live many days. Blood: red cells, 600,000; hæmoglobin, 30 per cent.; colour index, 2·5. Shortly after this she began to improve markedly. Oct. 5th: Red cells, 2,150,000; hæmoglobin, 50 per cent.; colour index, 1·1. At the convalescent hospital she continued to improve. Dec. 12th: Discharged, being of fair colour, able to walk about, though somewhat weak. Blood: red cells, 3,600,000; hæmoglobin, 85 per cent.; colour index, 1·2; stained film showed nothing abnormal.

Mr. REGINALD WILSON showed a case of Ruptured Intestine and Abdominal Wall. The patient, a youth, sustained an injury in which the intestine was ruptured and extruded through a rent in the abdominal parietes. The skin over the rent alone held; the gut lay immediately under it in a pool of fæces. Enterectomy was performed.

Mr. R. LAWFORD KNAGGS exhibited a series of cases of Fractures into Joints and Fractures Treated by Lane's Plates.

Mr. G. CONSTABLE HAYES and Dr. M. J. STEWART showed a Villous Papilloma of the Naso-pharynx Invading the Nasal Cavities.

Other cases were shown by Dr. L. A. ROWDEN, Dr. T. CHURTON, Mr. H. COLLINSON, Dr. J. GORDON SHARP, and Mr. MICHAEL A. TEALE.

## NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

*Exhibition of Specimens.—Impacted Ureteric Calculus.*

A MEETING of this society was held at Manchester on Dec. 16th, 1910, Dr. W. K. WALLS, the President, being in the chair.

Dr. FRANCES IVENS read notes and showed specimens of the following cases: 1. Localised Adenomyoma in a Tuberculous Fallopian Tube removed from a young married woman complaining of dysmenorrhœa and dyspareunia. The right tube was generally thickened with a nodule at the uterine end. Microscopically the tube showed typical tubercles. The nodule was composed of adenomyomatous tissue also showing giant cells and round-celled proliferation. Reference was made to the two similar cases described by Von Franqué and Parsons and Glendining. 2. Keratinising Adeno-carcinoma of the Uterus removed from a spinster aged 41 years. Dr. Pantland Hick investigated the tumour microscopically and found the growth to present in the older portions the appearance of a squamous carcinoma with cell-rests, but the glandular origin was evident in sections taken from the growing edge. 3. Chorion-epithelioma of the Uterus preceded by vesicular mole, and associated with unusual nervous symptoms. The mole, retained for seven months, was removed from a multipara aged 47 years. Involution took place, but two months later the uterus had enlarged, and profuse hæmorrhage occurred. Rigors and an elevated temperature took place three days before operation. After hysterectomy, on Oct. 3rd, 1909, severe shock was present, the temperature fell to 95° F., and stupor developed, followed by convulsions, ptosis, loss of sphincteric control, and increased tendon reflexes. Gradual recovery took place, but the illness was a blank in the mind of the patient. She went home weak, but otherwise well and able to walk. Two months later contractures developed and death took place in January, 1910. The cause of the cerebral symptoms was undetermined as no necropsy was obtainable. It was possibly toxæmia followed by encephalitis and cerebral softening, as the gradual onset negatived a metastatic embolus and no definite symptoms of cerebral tumour were present.

Dr. A. J. WALLACE showed an Enlarged Uterus removed from a woman aged 67 years. Before operation its upper border reached 10 inches above the pubis, and it measured 9¾ inches transversely. The enlargement had been noticed for three months only. On examining the tumour after removal it was found to be apparently a mere shell of uterine wall containing altered blood. The anterior wall had an average thickness of ¼ inch, the posterior of ¾ inch. Complete section of the "shell" demonstrated a layer of undoubted myomatous tissue of varying thickness in the posterior wall and an apparent thin layer of similar tissue in front. There was no trace of the cavity of the corpus uteri, except near the internal os, where a few flattened glandular elements suggested the remains of endometrical glands. The condition had had its origin from a myoma which had become cystic; hæmorrhage had occurred into the cyst, the resulting distension of which had produced obliteration of the endometrial cavity and enormous enlargement of the senile uterus.

Mr. R. FAVELL reported a case of Impacted Ureteric Calculus which had clinically simulated a uterine fibroid. It was discovered after the body of the uterus, which contained several small fibroids, had been removed. The left ureter was found dilated to the size of the forefinger and an impacted stone could be felt near the entrance to the bladder. The stone was removed and several ounces of purulent fluid allowed to escape from the ureter, which was then ligatured at the level of the pelvic brim. The lower end of the ureter was drained into the vagina by splitting the cervix. The kidney was markedly enlarged and lobulated. The patient made a good recovery, and later no enlargement nor tenderness of the kidney could be detected. The history showed that for three years before the birth of her first child (13 years ago) she had severe pain in the left side; but after the birth of the child the pain ceased, and did not recur until one year ago. Since then it had been steadily increasing, and for a month it had been very severe. There had never been any urinary symptoms beyond the scalding and occasional attacks of increased frequency of micturition.

Dr. W. E. FOTHERGILL exhibited: 1. Pregnancy complicated by Red Degeneration and Infection of a Fibroid. 2. Large Cyst of Uterine Origin with Fibroids.

Dr. T. B. GRIMSDALE showed: 1. Perithelioma of Uterus. 2. Sarcoma of Uterus.

Dr. W. BLAIR BELL exhibited: 1. Lutein Cyst of Ovary. 2. Torsion of Ovarian Cyst and Fallopian Tube.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF MEDICINE.

*Cœliac Axis Aneurysm treated by Operation, Introduction of Wire Tent.—Thrombosis of the Superior Mesenteric Vein.*

A MEETING of this section was held on Dec. 16th, 1910, Sir JOHN W. MOORE, the President, being in the chair.

Dr. JOHN LUMSDEN showed a man, aged 38 years, who had been engaged at a somewhat heavy class of work. There was a history of syphilis 16 years ago. Dyspeptic symptoms had been present since the beginning of the year. Abnormal epigastric pulsation was first noticed last August on his admission to Mercer's Hospital. In September last a tumour of the size of an orange was felt in the epigastrium, extending upwards under the left costal arch. Impulse was of a forcible and expansile character. A bruit was heard below the lump and conveyed along the aorta to both femorals. The femoral pulses were to be felt readily. The heart was normal but for accentuation of the aortic second sound. Blood pressure in radial artery was 110 mm. Hg. No pain. The diagnosis was saccular aneurysm of the aorta, probably from the neighbourhood of the cœliac axis. The patient was placed on large doses of

iodide of potassium, complete rest in the recumbent position with a modified Tufnell's diet being enjoined. No improvement taking place, after consultation with Mr. W. I. de C. Wheeler, operation was decided upon.

Mr. WHEELER described the evolution of surgery of the abdominal aneurysm. The patient exhibited resembled the vast majority in being a male, having a specific history, and having the aneurysm springing from the region of the cœliac axis. Mr. Wheeler had operated seven weeks ago and had introduced into the sac 150 inches of gilded wire in the form of a cage by the method of Colt and D'Arcy Power. For the first few days the aneurysmal pulsation was more tumultuous than before the operation, but since then there had been a distinct diminution of pulsation and hardening of the tumour.—Dr. WALTER G. SMITH and Dr. T. PERCY C. KIRKPATRICK discussed the case.—Dr. H. STOKES inquired as to the collateral circulation set up.

Dr. LUMSDEN, in reply, said that medical treatment of aneurysm in the past had been distinctly unsatisfactory. He had himself had four cases under his care—three men and one woman. The woman died suddenly six months after diagnosis, and no cause of death was discovered. One of the men died suddenly three months after diagnosis.

Mr. WHEELER, in reply, said that death was the result in nearly every case without operative treatment. The post-mortem examination, in cases where operation had been done, showed not a soft clot but a laminated clot, sometimes consolidated altogether, so that he did not see how the operation could be regarded as unscientific. Collateral circulation was well established, though by what means he did not know. No cases published, without operation, showed any cures; while there had been cures in every series with operation, so that he thought the operation was undoubtedly justifiable.

Mr. J. J. BURGESS read an account of a case of Thrombosis of the Superior Mesenteric Vein. The interest in this case was the comparative mildness of the abdominal symptoms and the prominence of those of a cerebral type, so that the finding at the necropsy was a surprise. The very few cases of primary thrombosis of this vein were referred to. The case was acute and terminated fatally in eight days with gangrene of portion of the jejunum. The marked feature was the early development of coma and the partial recovery from, and return to, that state, with symptoms of cerebral compression, evidently toxæmic.—Dr. H. C. DRURY, Dr. SMITH, and the PRESIDENT discussed the case, and Mr. BURGESS replied.

---

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 21st, 1910, Mr. W. Morley Willis, the President, being in the chair.—Dr. Ernest H. M. Milligan read a paper on Cerebro-spinal Fever. He described the signs and symptoms, diagnosis, and treatment, &c., of the disease, giving his observations on over 300 cases seen during the epidemic in Belfast in the City Fever Hospital, Purdysburn. Statistics were given of the frequency of the different signs and symptoms, the mortality rate in relation to age of those affected, the age incidence of the disease, and also the results of treatment by Flexner and Jobling's serum. The diagnosis was carefully gone into, stress being laid on the mode of onset. In all cases lumbar puncture was advised and the estimation of the opsonic index, as in doubtful cases the diagnosis can be settled by these means, the opsonic index being of great use after the sixth day of the disease; the fallacy of the Widal reaction as diagnostic from typhoid fever or typhus fever was noted. The great benefit derived from the use of Flexner and Jobling's serum was described and Dr. Robb's latest returns were given, the death-rate being 27·5 per cent. in 109 cases injected with serum. Dr. Robb's comparison of the death-rates outside hospital without serum with those inside treated with serum was considered of great importance, there being a reduction in the mortality of the difference between 85·2 per cent. and 26·6 per cent. in favour of the serum. Taking everything into account, Dr. Milligan considered that a reduction of the mortality by about 40 per cent. could be obtained by use of the serum. In the course of the paper the following conclusions were arrived at: 1. That owing to the occurrence of mild cases and toxic cases without meningeal symptoms the disease may be unrecognised unless lumbar puncture be done and the blood examined. 2. That the disease is spread largely by carriers and mild cases as well as by acute cases. 3. The search for these carriers and mild cases was advised to prevent spread of the disease. 4. That the intestinal mode of entry of the disease was probable. 5. That Flexner and Jobling's serum was of very marked value and should be given early. 6. The opsonic test was useful in diagnosis after the sixth day. 7. That sudden death after apparent recovery was always a possibility.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A joint meeting of this society and the Bradford division of the British Medical Association was held on Dec. 20th, 1910, Dr. W. Mitchell, the President, being in the chair. The following specimens and cases were shown:—The President: Some cases from the X ray department.—Dr. C. F. M. Althorp: (1) Case of Epithelioma of the Chin and Lower Lip operated upon three years ago; (2) specimen of Polypus of the Small Intestine causing Intussusception; and (3) specimen of Fibroid Uterus removed by abdominal hysterectomy.—Dr. A. Bronner: A case of Choroido-Retinitis simulating Retinitis Pigmentosa in a boy 8 years old with good vision.—Dr. T. Jason Wood: Specimens of (1) Fibroid Uterus and Broad Ligament Cyst removed by abdominal hyterectomy; (2) Calculous Kidney; (3) Malignant Growth of the Upper Jaw (Dr. Bronner's patient); (4) Scirrhus Cancer of the Breast with unusual amount of Ulceration of the Skin; and (5) Extra-uterine Gestation (Kaiserling preparation).—Dr. H. J. Campbell: Liver, Spleen, and Stomach from a case of Ascites in which death occurred suddenly.—Mr. T. Wilmot: Kidneys from a case of Puerperal Eclampsia.—Dr. F. W. Eurich: Cases of (1) Thomsen's Disease; (2) Cardiac Infantilism; (3) Tabes in an old woman; and (4) Psychosis of Peripheral Neuritis. He also demonstrated a Clinical Method for the Detection of Blood.—Dr. A. Little and Mr. Goyder: Three cases after Decompression Operation for Intracranial Tumour: (1) tuberculous tumour in the region of the internal capsule; (2) tumour of pituitary body; and (3) tumour in the posterior cranial fossa.—Mr. Goyder: (1) Five cases after operation for Cleft Palate; (2) Five cases after operation for Hare-lip; (3) specimen of Gangrenous Small Intestine removed from a case of Strangulated Umbilical Hernia; and (4) specimen of Prostate removed by Young's Perineal Method.

BATH CLINICAL SOCIETY.—A meeting of this society was held on Dec. 2nd, 1910, Mr. F. Lace, the President, being in the chair.—Mr. Donald Ackland read a paper on Oral Sepsis, showing that many obscure illnesses and pathological processes are frequently the result of, or are secondary to, septic conditions of the mouth, nose, and nasal sinuses, the gastro-intestinal tract and glands opening into it becoming infected from oral, nasal, and auditory suppurative processes, deformities such as arthritis and tenosynovitis in many instances being but symptoms of the primary trouble—the oral sepsis. Of the conditions included under this heading pyorrhœa alveolaris and its treatment by the vaccine method was more especially discussed.

---

THE ROYAL SANITARY INSTITUTE.—A provincial sessional meeting will be held at Bradford on Feb. 3rd and 4th, 1911. The members will meet at the Town-hall, Bradford, at 2.30 P.M., and proceed to visit the open-air school at Thackley. In the evening a discussion will take place in the council chamber of the Town-hall on "School Clinics." The chair will be taken at 7.30 by Dr. Louis C. Parkes, chairman of the council of the Institute, and the debate will be opened by Dr. L. A. Williams, medical superintendent to the Bradford education authority. The following have consented to take part in the discussion: Dr. J. R. Kaye, Dr. S. G. Moore, Dr. E. M. Smith, Dr. A. E. L. Wear, and Dr. Ralph P. Williams. On Feb. 4th members will meet at the Town-hall, Bradford, at 9.45 A.M., to inspect the school clinic, after which a special tramcar will be in readiness to take them to see the municipal dairy at Heaton. In order to prevent disappointment it is essential that those wishing to be present at the visits should notify Dr. W. Arnold Evans, Medical Officer of Health, Health Department, Town-hall, Bradford, or the Secretary of the Institute, not later than Jan. 27th, so that proper arrangements may be made in due time. Tickets for admission of visitors, who are invited to intervene in the debates, may be had on application to the same gentlemen.

# Reviews and Notices of Books.

*A Handbook of the Surgery of Children.* By E. KIRMISSON, Professor of the University of Paris, Surgeon to the Hospital for Sick Children, &c. Translated by J. KEOGH MURPHY, M.C. Cantab., F.R.C.S. Eng., Surgeon to the Miller General Hospital for South-East London, Senior Assistant Surgeon to the Paddington Green Children's Hospital. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1910. Pp. 822. Price 20*s.*

BOOKS which give to the student a superficial veneer of knowledge sufficient to enable him to emerge successfully from examinations, and teach no lasting or profitable lesson, whose aim is to include in the smallest bulk the greatest possible amount of material, when they have served their immediate purpose are done with and forgotten. Such treatises, states Professor Kirmisson, suit neither his taste nor his years. We therefore turn expectantly to find within his volume lessons that are really useful both to the medical student who is anxious to acquire sound principles for the practice of his profession and to the practitioner. The author's aim has been to paint a picture in which the principal facts will be found among the high lights, and in the shadows all that is of less importance. The translator has endeavoured faithfully to reproduce the distinguished author's opinions as well as his words, not attempting in any way to alter the text, but adding footnotes where an explanation or addition seemed necessary. And we may say at the outset that the two great subjects which dominate infantile surgery—namely, malformations and diseases of the locomotor system—are very fully treated, and on such conditions as appendicitis, mastoiditis, diseases of the throat, intussusception, &c., a sound practical knowledge of surgery is inculcated, that knowledge which is so much more required in the treatment of these conditions than exceptional skill in operative surgery.

The work is divided into four parts, dealing respectively with surgical affections of congenital origin, injuries in childhood, inflammatory lesions and disorders of nutrition, and tumours. In a short appendix to this, the English edition, Dr. Cecil Hughes has added notes on the production of anæsthesia in children which should be of use both to the surgeon and anæsthetist. Surgical affections of congenital origin are dealt with in regional sequence. Preceding the description of the congenital malformation of each region is a short and lucid account of the development of the part and a statement of the embryological considerations that arise. In cases in which satisfactory results are known to have followed particular surgical procedures the methods are given for surgical cure, but the author does not hesitate to state his disagreement with those who advocate craniectomy for microcephaly, and other proceedings which experience has shown are purely theoretical and futile. All the well-known and accredited plastic operations are fully described, and this part, as well as the rest of the book, is profusely illustrated with drawings of classical types, the object being to make descriptions intelligible rather than depict particular cases. The treatment of club-foot is fully described and illustrated, the author favouring the treatment in two stages as originally recommended by Adams, and for cases of long standing with severe bony malformations he has devised a modification of Phelps's operation of mid-tarsal arthrotomy. For congenital dislocation of the hip the method of Lorenz has now proved itself efficacious and safe in many hands. The author gives a moderately full description of a bloodless method. The technique of the application of the plaster apparatus for fixation of the limbs in full abduction is one which has the most important bearing upon the final result of the operation. It is therefore a surprise to find on p. 272 of the book a figure depicting a plaster sheath which extends above to the level of the ribs and below to midway between the knee and ankle, thus entirely preventing the alternate flexion and extension of the knee-joint each day which is mentioned by the author as being necessary. In those cases in which the patients have passed the age for which the bloodless method is available the author rightly points out the need for care in recommending raising of the foot, which in loose joints is productive of great harm.

Part II. deals with injuries in childhood, which are first considered generally and then in detail. A very full and particular account is given of injuries involving the elbow-joint, and sound principles of treatment are inculcated. Under this heading are included the cicatricial results of burns and foreign bodies in the auditory and respiratory passages. Inflammatory lesions and disorders of nutrition occupy over 400 pages, and are dealt with in 12 chapters as follows: (1) Osteomyelitis; (2) Tubercle of the Bones and Joints; (3) Rickets and Other Defects of Development of the Skeleton; (4) Syphilis of the Bones and Joints; (5) Deformities which are the Result of Affections of the Nervous System; (6) Middle-ear Disease and its Complications; (7) Affections of the Pharynx and Nasal Fossæ; (8) Inflammation of the Cervical Glands; (9) Maladies of the Thorax; (10) Abdominal Affections; (11) Affections of the Anus and Rectum; and (12) Maladies of the Genito-urinary System. It is here, perhaps, more than elsewhere, that an opportunity is afforded the author to place before his readers in a conspicuous manner the practical and useful lessons which he teaches, leaving in shadow the less important facts, thus justifying the aim of his writing. In this we think he has well succeeded, and the reader in search of practical information, sound principles, and reliable guidance in difficulties will find them here. It is not the author's purpose to mention all the forms of treatment in use, but only those which to his personal knowledge have proved satisfactory, and in consequence many well-recognised forms of treatment are unnoticed. Nor is it possible for a single individual to write with equal authority on all departments of surgery. We therefore have found instances in which we disagree with the author in what he considers to be the best means of carrying out the sound principles of treatment which he lays down. Nevertheless, it is a book which we can recommend to the medical man in active practice as one which he will at all times find useful and thoroughly reliable.

---

*A Text-book of Pathology for Practitioners and Students.* By JOSEPH MCFARLAND, M.D., Professor of Pathology and Bacteriology in the Medico-Chirurgical College, Philadelphia; Pathologist to the Philadelphia General Hospital and to the Medico-Chirurgical College, Philadelphia; Director of the Henry Phipps Institute, Philadelphia, &c. Second edition, thoroughly revised. With 437 illustrations, a number in colours. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 856. Price 21*s.* net.

PATHOLOGY has so far extended its boundaries and has come to occupy so important a place in the medical curriculum that it is an ambitious undertaking to endeavour to deal with the whole subject in a single volume: the prevalent tendency is to divide it into general and special pathology and to devote separate volumes to each of these. Professor McFarland states that his work was primarily intended for students working for the degree of Doctor of Medicine, and that he desired to explain the principles of pathology rather than to deal with controversial questions. No doubt

there is an advantage in collecting all the necessary information in a single volume, especially in facilitating reference, but the result is a bulky volume in rather small print, with some of the less important sections in still smaller type. But our fault-finding stops there. The book is a very useful one—the subjects are dealt with clearly and nothing essential is omitted. The arrangement of the subject matter is good; facts are given rather than discursive presentations of ill-digested observations and theories. Although the type is small the book is well printed, the headings are set out in thick type, and the illustrations are numerous and well chosen.

In the section of general pathology the etiology of disease is considered from the pathological standpoint, and then the defects of development with the various malformations and anomalies resulting are described. A chapter follows on the pathology of nutrition, in which derangements of digestion, assimilation, secretion, and excretion are briefly reviewed. Abnormal conditions of the circulation are described, but in somewhat less detail than one might expect in a work of this importance. An interesting chapter on the characteristics of cell life includes a brief though clearly written account of the fundamental characteristics, both structural and physiological, of cells. Regenerative and retrogressive tissue changes are next described, and the accounts given of the individual degenerations and infiltrations may be mentioned as being concise and clearly defined. This chapter is one which is worthy of special commendation. Under the heading of progressive tissue changes hypertrophy and tumour formation are included. Tumours are discussed at some length, and the classification adopted is that of Professor Adami into lepidic and hylic, but certain modifications are introduced in some details. A chapter is devoted to a general consideration of parasitism, in which the more important vegetable and animal parasites are classified and briefly described. The descriptions given of the parasites of malarial fevers, of piroplasmosis, and of the various forms of trypanosomiasis are very good and well illustrated.

The difficult subject of immunity is dismissed with rather ess consideration than its importance and intricacy demand. A short description of Ehrlich's side-chain theory is given, but it is so brief that it is doubtful whether a student would be able to derive a clear conception from it of this far-reaching hypothesis. The general pathology of infection and of the infectious diseases is next considered. Under this heading the phenomena of inflammation are included. Professor McFarland gives a useful description of this process, though he appears to minimise the part played in it by the tissue cells. The general characters of the specific or infective granulomata are next given. These are dealt with more fully, and descriptions will be found here of the general characters of the lesions of tuberculosis, leprosy, glanders, actinomycosis, mycetoma, cattle farcy, rhinoscleroma, mycosis fungoides, aspergillosis, and syphilis. These accounts are copiously illustrated by figures representing the macroscopic and microscopic characters of the typical lesions of these conditions.

The second part of the book is devoted to special pathology and follows conventional lines, the diseases of special organs or systems being considered in separate chapters. The pathology of the blood is first dealt with, the variations in its characters under different conditions being clearly outlined. The general characters of the individual primary and secondary anæmias are then given, and the blood picture in each is differentiated, being also well illustrated by coloured reproductions of the appearances of stained blood films. Some of the less common blood conditions such as purpura are only very briefly referred to. The chapter on diseases of the cardio-vascular system commences with a short account of congenital malformations. The morbid changes occurring in the pericardium and myocardium are then dealt with, and endocarditis with its results is discussed. A bald discussion of the physiology of the circulation under abnormal conditions is included. In connexion with diseases of the blood-vessels, the condition of arterio-sclerosis and its results are clearly described, but the characters of syphilitic mesaortitis are not defined as clearly as might be.

Diseases of the digestive system are well classified, and the descriptions given of all of the important morbid changes are good. The chapter devoted to these conditions extends to 87 pages, and within this compass is included a great deal of useful and carefully weighed information. Diseases of the respiratory system are adequately described. The account given of pulmonary tuberculosis, though brief, contains all the essentials, and the description of empyema may be mentioned as worthy of special note. Diseases of the skin are dealt with in sufficient detail, and the chief characters of the various eruptions, including those of the exanthemata, are dwelt upon.

Diseases of the spleen, lymphatic nodes, thymus gland and bone marrow are considered together, and the chief morbid conditions affecting them are enumerated and briefly discussed. In the chapter on diseases of the motor apparatus, the abnormal conditions affecting the bones and joints are carefully described, though acute rheumatism, rheumatoid arthritis, and gout might perhaps have been treated at greater length with advantage. Diseases of the nervous system are classified and discussed on ordinary principles, and some good reproductions of sections prepared to show degenerations are included. The remaining chapters are occupied by diseases of the reproductive system and of the urinary system respectively, and call for no special comment.

The book as a whole may be recommended as a useful text-book for students and as a work to which the practitioner may refer for general information in regard to pathology. There is a good index, which should facilitate its use for this latter purpose. The writer has obviously had considerable experience of teaching, and has presented his subject-matter clearly and from a practical standpoint. There are a few mistakes in spelling which have escaped correction. Thus the trypanosome of sleeping sickness is referred to as "trypanosoma gambensi" on page 289, and as "trypanosoma gambiensi" on page 305. "Ali nasi," on page 381, and "epuli," on page 471, are other examples. In regard to the digestion of proteins, the new nomenclature is not adopted, and these bodies are referred to under the old name of "proteids."

---

*A Manual of Surgical Anatomy.* By CHARLES R. WHITTAKER, F.R.C.S. Edin., Senior Demonstrator of Anatomy, Surgeons' Hall, Edinburgh. With 48 illustrations in the text. Edinburgh: E. and S. Livingstone. 1910. Pp. 248. Price 5*s.* net.

THIS book, which is offered to the student as providing him with the outlines of the subject, is compiled from the notes of the author's lectures delivered at the Surgeons' Hall, Edinburgh. As a series of lecture notes upon surgical anatomy the book fulfils its function well, for it is brief and dogmatic, fairly well up to date, and much of its information is tabulated. Such tables as those which give the lymphatic supply of various organs are especially useful, and they will help the student in the revision of his subject for examination purposes. The book makes no pretence at giving an exhaustive system of surface markings, but in the case of the more surgically important regions the most noteworthy lines are mentioned. Some of these are not to be recommended. The directions given for trephining for the posterior branch of the middle meningeal artery (p. 12) at 1¾ inches behind

the external angular process and ¼ inch above Reid's base line, would land the operator in most cases in serious difficulty. The statement that the symphysis pubis cannot be palpated in the male because it is masked by the root of the penis and the penile muscles (p. 183) requires some qualification, as does also the dogmatic assertion that there is no anatomical middle lobe to the prostate (p. 176), and that the uvula does not reach to the dorsum of the tongue (p. 48). Of the clerical slips needing alteration we notice that the term "superficial fascia" is used when the author obviously means the superficial layer of the deep fascia (p. 76), and that the lymphatic glands described as the "supraclavicular" set all lie below the level of the clavicle (p. 93). The habit of dissecting the sole of the foot reversed from its natural position has also led the author into using the word "downwards" instead of the correct "upwards" in describing the arterial supply of the sole (p. 235). There are several minor blemishes about the book, but all are easily corrected in any subsequent edition, and when the book appears again it is to be hoped that the author will include more references to the anatomy of the female body than the mere description of the mamma, which is the sole representative of female anatomy in the present work.

The illustrations to the book are for the most part original and are diagrammatic. There are very few improvements made in the perfecting of various industrial methods that do not bring some drawback in their train; and the cheapening of line reproduction processes has proved the undoing of the meagre draftsmanship of modern anatomy. That an illustration is intended only to be diagrammatic is too often taken as an excuse for its careless drawing, and it is hard not to regret that process work is so cheap that the illustrator need not think twice before sending a very inferior piece of work for reproduction. Had reproduction been more laborious and costly, we are inclined to think that Mr. Whittaker would have hesitated to submit some of his figures to the process of block-making. Fig. 2 is an example of careless draftsmanship. The figure is intended to give the surgical guides to the middle meningeal artery: the pterion is abnormally represented, no indication of the great wing of the sphenoid is given on the surface of the skull, and the temporal bone appears to articulate with the malar; in addition to this, there is the appearance of an extra suture across the occipital bone. Fig. 4 is again a very poor piece of work and cannot prove of any real use as a surgical guide. More care might have been expended also on the naming of the illustrations, for "T.S. middle left leg" and "T.S. penis" might be expanded with some advantage. These are evidences of hurried work which should not be permitted to creep in and spoil the effect of a manual intended to teach the precise application of anatomy to the science of surgery, and having good claims to do so.

---

*The Principles and Practice of Medical Jurisprudence.* By the late ALFRED SWAINE TAYLOR, M.D., F.R.C.P., F.R.S. Sixth edition. Edited, revised, and brought up to date by FRED. J. SMITH, M.A., M.D. Oxon., F.R.C.P. Lond., F.R.C.S. Eng., Physician to, and Lecturer on Medical Jurisprudence at, the London Hospital. In two volumes. London: J. and A. Churchill. 1910. Vol. I., pp. 950; Vol. II., pp. 887. Price £2 2*s*.

THE general scope and nature of this excellent text-book are too well known to require any words of explanation from us. The editor explains in his preface that the chief changes introduced into the sixth edition are a further reduction in the number of woodcuts, thus leaving more room for letterpress without increase of bulk, some reduction in the space occupied by the criminal aspects of wounding, and a considerable reduction in the pages devoted to lunacy. These omissions have been counterbalanced by large additions to the discussion on the legal relationships of anæsthesia and an expansion of the treatment of assurance, rendered necessary by the prominent position which actions under the Workmen's Compensation Act of 1906 are now assuming in legal medicine.

Dr. Smith has very properly devoted considerable space to the various points which may occur in cases brought into court under the Act just mentioned. The question of what is an accident has now assumed complexities and proportions unthought of some years ago, and medical practitioners are now frequently confronted with the legal aspects of injury to workmen in some form or another. Dr. Smith divides the subject into four divisions: (1) The defining of an accident apart from its results; (2) the relation of an accident to pre-existent disease; (3) the relation of an accident to subsequent disease; and (4) trade diseases directly due to the nature of employment. Numerous cases are quoted to show the problems which may come before the courts when damages are claimed for an injury received by a man in the course of his employment, and by close attention to the remarks and study of the cases which are related a large amount of valuable information may be acquired. Our columns have shown persistently since the Act became law how difficult are many of the questions involved, and Dr. Smith deals with many of them skilfully.

The administration of anæsthetics has of late been much and vigorously discussed, and Dr. Smith's remarks on the subject are specially interesting as they are expressed boldly and are evidently the result of careful thought and cogitation. There is certainly need for legislation considering the enormous number of anæsthetics that are administered. His suggestions as to the broad lines upon which a Bill should be promoted are as follows:—(1) That only properly qualified persons should administer an anæsthetic and receive the protection of the law; (2) that it shall be possible for a public inquiry to be held on a fatal case; (3) that a public inquiry should not necessarily follow on a death unless the person giving the anæsthetic was unqualified; (4) that the option of initiating an inquiry shall rest with any of the persons concerned who may feel dissatisfied with the result without an inquiry—i.e., the surgeon, the anæsthetist, or the nearest relative, guardian, or executor of the deceased, or with the lay committee of the institution in which the death occurred; (5) that the form of public inquiry shall take some other form than a coroner's inquest as at present constituted—i.e., a special jury of some kind; (6) that practical and theoretical instruction in the administration of all the anæsthetics in common use shall be demanded of every candidate for a medical qualification, and also of every candidate for a dental diploma. A Bill passed on these lines would to a certain extent cover the ground of the Bill now under consideration, but legislation exactly in accordance with the suggestions made is not very probable. We are strongly of opinion that the coroner's court is not the right place to inquire into fatalities under anæsthesia; but Dr. Smith's suggestions for a Bill include matters of education which can be, and will be, dealt with by the General Medical Council.

We once again congratulate the editor, Dr. F. J. Smith, on the result of his labours, which are heavy and responsible. Taylor's "Principles and Practice of Medical Jurisprudence" still holds a permanent place in text-books dealing with the subject and will be found of the first value to members of the legal profession as well as to medical practitioners.

---

## LIBRARY TABLE.

*Medical Service in Campaign. A Handbook for Medical Officers in the Field.* By Major PAUL FREDERICK STRAUB, Medical Corps (General Staff), United States Army. Illustrated. Philadelphia: P. Blakiston's Son and Co. 1910.

Price $1.50 net.—This neat little handbook, which has been prepared by Major Straub under the direction of the Surgeon-General of the United States Army and published by authority of the War Department, contains the substance of a series of lectures delivered by the author at the medical department camp of instruction at Antietam. While primarily written for medical officers of the regular army and National Guard, it should prove most useful not only to other officers but also to students of military subjects at service schools in the United States of America, who must necessarily give some consideration to the disposition of the medical service in all of the larger tactical problems. During recent years the military forces of the United States have been largely reorganised, and the medical department has shared in this improvement. Particular care is taken to select candidates for commission as military surgeons who are exceptionally well grounded and trained in the duties of their profession. The approved candidates are given a year's instruction at the army medical school in subjects specially indicated for the service. The writer very rightly points out that army medical officers are not merely *healers* of disease, but that their efficiency also depends in *preventing* disease, and thus helping the fighting line of its encumbrance of sick. Chapter II. deals with collateral military subjects, such as preparation for field service, orders, map reading, weapons, casualties, and transportations. The sections on weapons and casualties are most interesting, as the range and efficiency of modern firearms are discussed in a practical manner. A statistical table showing the casualties from various campaigns is given. The loss in the individual battles in the Russo-Japanese war was much greater than in previous wars, being 16 to 20 per cent., as against 7 per cent. in the Franco-German war of 1870-71. At the battle of Mukden the Russians lost 2·9 per cent. killed and 16 per cent. wounded, and the Japanese 4 per cent. killed and 17 per cent. wounded. At Sedan 35 years previously the Germans lost *under* 1 per cent. killed and 1 to 3·9 wounded, and the French lost 2·7 killed and 1 to 4·6 wounded. "It would appear, therefore," says Major Straub, "that the battles in the Far East were 'bloody,' not because of their longer duration, but also on account of the high efficiency of the weapons used." Chapter IV., dealing with administration, and Chapter V., describing battle dispositions, both form interesting reading. Major Straub has compiled a well-turned-out little book on the medical service arrangements of the United States army which should prove valuable to the officers connected with this service and a useful work of reference for those of our officers who wish to study the medical arrangements of other armies.

*Conversations with Women Regarding their Health and that of their Children.* By A. RABAGLIATI, M.A., M.D. Edin., F.R.C.S. Edin., Honorary Gynæcologist (late Honorary Surgeon), Bradford Royal Infirmary. Bradford: William Byles and Sons. 1910. Pp. 318. Price 5*s.* net.—Dr. Rabagliati has certainly a somewhat novel creed to expound, as we learn when he informs us in his preface that energy is the immediate cause of material substance, and that he does not believe that material substance is the cause of energy. He holds that "gravitation is not a property of matter but a form of the universal energy which incorporates itself in material substance in order to its own manifestation." Energy is to be regarded as flowing into and procreating the atom at one stage, and flowing out again coincidently with the breaking up of the atom at another stage. From the point of view of the author matter is not eternal, but energy is. In these conversations human bodies are viewed as procreations by the human power of life (what the author terms anthropino-zoo-dynamic) to be fitting habitations for the manifestations of all the powers of human life. These powers act through the functions of organs, and the fundamental or primary one of these, from the author's point of view, is nutrition. According to Dr. Rabagliati the fundamental character of nutrition is proved by the fact that the first step in development is the turning in of the outer layer of the embryo to form the body cavity, which body cavity is the beginning of the digestive tract! He then goes on to say that when "we perceive this point clearly and adapt our physiological conduct to it we incidentally add a large number of years to healthy, happy, and efficient human life." As he remarks, it is certainly very curious and very interesting, but we must confess we are completely unable to follow either the author's argument or his meaning. On the application of this idealistic theory the author has built up a book dealing with the health of women and that of their children.

*Golden Rules of Refraction.* By ERNEST E. MADDOX, M.D. Edin., F.R.C.S. Edin. Bristol: John Wright and Sons, Limited; London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. Pp. 96. Price 1*s.*—This is the third edition of what the author describes as a "little miniature of a subject to which only a large volume could do justice." The description is accurate. It is intended "chiefly for the help of general practitioners who may be commencing the study of refraction." Unless the general practitioners are exceptionally situated in that they are able to correct many refractions under the supervision of a competent teacher we fear that the book will be of little value to them. For the medical student who approaches the subject seriously and under proper control it will form a very useful reference book to carry in his pocket, and even the expert may be recommended to read it through, for he will find several valuable "tips" which we do not remember to have seen collected elsewhere. Moreover, he will find nothing to cavil at in the teaching, as was, indeed, to be expected in a book on this topic by Dr. Maddox.

*The Treatment of Syphilis by the Ehrlich-Hata Remedy (Dioxydiamidoarsenobenzol).* A Compilation of the Published Observations by Dr. JOHANNES BRESLER, Chief Physician to the Provincial Medical Establishment at Lüben, Silesia. Second edition, much enlarged, with the portraits of Ehrlich and Schaudinn. Translated by M. D. EDER, M.R.C.S. Eng., L.R.C.P. Lond., with an abstract of the most recent papers. London: Rebman, Limited. Pp. 122. Price 2*s.* 6*d.* net.—This is a translation of the second edition of Dr. Bresler's pamphlet, and it consists mainly of abstracts of the chief papers which have been published on the use of "606," especially those which have appeared in Germany. There is an appendix by the translator which contains *résumés* of those articles which have been published since the publication of the original German work, and this notices most of the papers which have appeared in this country. The book will prove chiefly of use as showing what has already been written on the subject. The information is somewhat undigested, but this will not in any way militate against its use as an introduction to the subject.

*Die Mikroskopischen Untersuchungsmethoden des Auges.* Von Dr. S. SELIGMANN. Berlin: S. Karger. 1911. Pp. 324. Price, paper, M.8; boards, M.9.20.—Dr. Seligmann's book has proved its utility and is improved by being brought up to date in this second edition. The division into two parts, general and special, and the main features of the work remain the same. There are useful bibliographies appended to the sections. New methods of staining for fat, glycogen, axis cylinders, neurofibrillæ, &c., are described. Sections on staining blood cells and bacteria have been added. We find no mention of the advantage of freezing the eye before cutting it preparatory to making microscopical sections.

Where topographical detail is so important, as in most preparations of the diseased eye, this method is to be recommended strongly. On the other hand, it is, in our opinion, unnecessary to make holes in the walls of the globe to allow fixing fluids to penetrate. Even sublimate solutions, such as Zenker's, which we concur with the author in advocating, penetrate quite satisfactorily without running the risk of damaging the structures by the method which the author advises. The directions are precise and reliable, and the book is the most useful one on the subject which we have seen.

*First-Aid to Injured and Sick.* By J. F. SUTHERLAND, M.D. Edin. London: Houlson and Sons. Edinburgh: John Menzies and Co. Thirty-sixth edition, revised and enlarged. Pp. 32. Price 3*d*.—This is a waistcoat-pocket memorandum that will be useful to the general public, particularly those whose occupation brings them especially into contact with accidents.

*Herbert Fry's Royal Guide to the London Charities, 1911.* Edited by JOHN LANE. London: Chatto and Windus. Pp. lvi.–375. Price 1*s*. 6*d*.—This handbook, now in its forty-seventh issue, serves a double purpose. First, it directs the needy to those charities that will best succour their special source of distress; secondly, it sets forth the aims, incomes, needs, and other particulars of organised charities, so that those who may be prompted to bestow some portion of their income may so inform themselves as to make a judicious choice. The past year has been a very bad one for charities, the main reasons suggested for this being the death of King Edward, which has increased distress by lessening the usual avenues of employment, and secondly the facts that the financial changes introduced by the Budget has made business wavering and uncertain, while the changes in the licensing law threaten many with severe curtailment of their incomes, and the increased death duties have necessarily diminished legacies for charitable purposes. At Christmas-tide, however, hearts and purses are opened, and this little book will come to the aid of many who would be willing to give if they only knew how to bestow their mite judiciously.

*The Religions and Philosophies of the East.* By J. M. KENNEDY. London: T. Werner Laurie. Pp. 296. Price 6*s*. net.—Mr. Kennedy tells us in his preface that he has attempted to apply the Nietzschian standards of good and bad to the main principles of the more important religions of the East. To do this he gives a short account of the chief beliefs and tenets of Brahmanism, Buddhism, Mohammedanism, Judaism, Confucianism, and Shintoism, together with a few remarks on Parseeism and Mithraism. Advanced thinker as Mr. Kennedy would appear to be, his opinions will be anathema to the modern democrat, for we find him saying on p. 267 that "the religion of men of inferior intellects must be prescribed for them by the higher order of men, and not, as is usually the case at present, *vice versa*." And again, p. 32, "In the 'civilised' countries of the West the dregs of society are permitted to rule the whole community." It is no part of our duty to argue for or against the correctness or otherwise of these sentiments, but we can say that Mr. Kennedy has produced an interesting book. On account of the very wide range of subjects with which it deals in a brief manner it is necessarily superficial, but the reader will find at the end of the book a very fairly complete bibliography of works dealing with the various religions by a study of which he may read up the subject more at length.

*New Year's Diaries and Calendars.*—To most medical men a pocket diary is essential and to many a desk diary in addition. They therefore form useful and acceptable New Year gifts. As in former years, we are able to commend in this respect the productions of John Walker and Co., and the well-known original Letts's diaries, published solely by Cassell and Co. Messrs. Walker continue to produce neat and convenient pocket-cases containing slip-in diaries and note-books of various sizes. The same firm's Pearl diary, of waistcoat-pocket dimensions, is particularly neat. Letts's diaries are so well known that they need no description. They are issued in various sizes, with or without interleaved blotting pages. The accident insurance coupon is not omitted, and we are informed that claims amounting to £3500 have been paid to holders of Letts's diary coupons. They also publish a Nurses' Report Book and Diary, which should prove a great convenience to district nurses, and a convenient and narrow medical visiting list. We have also received physicians' and surgeons' visiting lists, published as neat pocket-books, by Hazell, Watson, and Viney, John Wright and Sons of Bristol, and Rudall, Carte, and Co., containing a large amount of useful information in the preface.

## JOURNALS AND MAGAZINES.

*Brain, a Journal of Neurology.* Edited by HENRY HEAD, M.D. Camb., F.R.S. Vol. XXXIII., Part 130. London: Macmillan and Co. Price 4*s*. net. Yearly 16*s*. net.—This journal maintains its high reputation, and continues to attract important and interesting papers. The present number contains an account of an exhaustive research on the functions of the "Mesencephalic Root of the Fifth Nerve," by Sir Victor Horsley and Dr. Otto May; a paper by Dr. Harvey Cushing, which we have noticed elsewhere, on "Strangulation of the Sixth Nerves by Lateral Branches of the Basilar Artery in Cases of Brain Tumour"; a paper on "Tumours of the Third Ventricle," by Dr. Weisenburg; and one on "Central Nervous Response to Peripheral Nervous Distortion," by W. A. Osborne and Basil Kilvington. There are thus contributions from England, from the United States, and from Australia, all of them of more than usual interest.

*The Birmingham Medical Review.*—In the November issue of this magazine is published the first of the Ingleby lectures for 1910, delivered by Professor R F. C. Leith. It deals with so-called simple or benignant tumours of the uterus, including the important subject of fibroids. Dr. W. A. Potts writes on the laws of heredity as bearing on the problem of the feeble-minded, a condition which the researches carried on at the Galton laboratory show to be inherited.

*The Medical Chronicle.*—In the November number is an address by Mr. C. B. Lockwood dealing with the relationship borne by carcinoma, sarcoma, and endothelioma respectively to inflammation. He holds that all these conditions own the same cause. For the purpose of his thesis he attempts one more definition of inflammation to add to the many already proposed—viz., that inflammation is the increased number of cells in a part caused by an irritant. Dr. Robert Lakin continues his study of the blood and urine in conditions associated with dropsy, but does not reach any very definite conclusions. To the December issue Dr. W. B. Warrington contributes a most interesting paper on neurasthenia, setting forth the theories which have recently been propounded in explanation of this and allied functional disorders dependent on alterations in the synapses or junctions between the neurons. Dr. R. T. Williamson contributes a review of recent literature dealing with medical geography.

*Edinburgh Medical Journal.*—The existence of a form of multiple inflammation of joints, simulating rheumatism but connected with tubercular infection, has been much ventilated in France, but has received little attention in this country. Professor Alexis Thomson, therefore, does good work in calling attention to the investigations which have been made into this pathological condition. His address on

this subject, published in the December number of this journal, is well worthy of careful perusal. Dr. John Strachan sets forth some novel views as to the functions of the corpuscles and fibrin of the blood in his Harveian Oration, delivered at Edinburgh and published in the same journal. Other papers are those by Dr. Lewis C. Bruce on the importance of physical examination in mental cases, by Dr. M. Douglas on infection of the urinary tract by bacillus coli, and by Mr. J. Crawford Renton on gastric and duodenal surgery.

*Contemporary Review.*—The January number of the *Contemporary Review* covers a large range of subjects, and contains one article of distinctly medical appeal—an explanation of the message of the late Professor William James. As Professor James would have admitted, "pragmatism," as he left it, did not attain to any final expression, but none the less Professor Jacks finds its author a thinker of the first rank, "not always unconfused it is true, but yet with a clear vision ahead of him, a range of varied philosophical experience behind him, and with a great human purpose in his heart." The article is a closely written investigation of the controversies introduced by Professor James into the philosophical world, and those interested in such high dialectics will do well to read it.

The issue of the *Cornhill* for January shows that this vigorous example of the great Victorian magazines is as good to-day as ever. Its more immediate congeners have perished, but it remains strong in interest, literary in character, and agreeable in form. The article most distinctly of medical interest is one by Mrs. S. A. Barnett upon Town Planning; but our readers may be interested in a series of examination papers on the works of famous authors, which is started by 12 questions upon the "Essays of Elia" propounded by Mr. E. V. Lucas; while Mr. Benson's story of the life of "J. K. S." has considerable psychological importance. Two serial novels are begun, one by Mrs. Humphry Ward and the other by Mr. and Mrs. Egerton Castle.

*The Burlington Magazine.*—The *Burlington Magazine* begins the year with a very good number, containing a great deal of information useful not only to those who desire artistic discussions, but also to those who are specialising as collectors in different directions. The editorial article on National Memorials is a timely reminder that to obtain a satisfactory memorial to a dead king, or to any other celebrity, is in this country not easy. The editors of the *Burlington Magazine* suggest that it is not enough to throw open the competition to all British artists without distinction, so long as the jury consists of the type of official artists to whom in the end the commission will certainly be given. Mr. Cescinsky continues to write on the furniture of the Gillow "Cost-books," and to collectors of furniture these articles have many points of interest. Mr. Clutton Brock, in a very sagacious paper, attempts to explain what the Post Impressionists would be at. His article will be more convincing to those who have not seen the pictures, but those who have seen them will coincide with his closing sentiment in which he says that the "public (British) seems to find them amusing, and after all it is better to be amused than to be bored." There is an interesting note on the work of the brothers Le Nain, a selection of whose paintings are now on exhibition at the Burlington Fine Arts Club.

ISOLATION HOSPITAL EXTENSION AT COVENTRY.—The Coventry city council has had before it a scheme for enlarging the present accommodation of 60 beds by an additional 40, which, with the population estimated at nearly 100,000, will give 1 bed per 1000 of the number of inhabitants. The cost of carrying out the scheme, which the council has approved, is put at £11,500. It was also decided, at the same meeting, to appoint a disinfector and another assistant-inspector of nuisances, and to erect a public mortuary at an estimated cost of £2150.

# THE LANCET LABORATORY.

### CALOGEN BLOCK.

(CHAS. ZIMMERMANN AND CO., 9 AND 10, ST. MARY AT HILL, LONDON, E.C.)

NOTHING could be more convenient and effective for the production of formaldehyde vapour than the calogen block. In a trial we made with it torrents of formaldehyde vapour were given off, and it is important to add that the formaldehyde so evolved is moist. It is well known that dry gases are not effectual as germicides. The block consists of a column of permanganate with some bichromate of potassium, and on moistening this with formaldehyde solution the gas is rapidly disengaged. In actual operation the block is placed in a clean pail or other metal receptacle, and from 5 to 6 ounces are poured over the column. It is as well to cover the bottom of the pail with a few ounces of water before starting the reaction. This simple method is obviously useful for aerial disinfection, in rooms, schools, hospitals, and places of public resort generally.

### ALBULACTIN.

(A. WÜLFING AND CO., 12, CHENIES-STREET, LONDON, W.C.)

Albulactin is described as the vital protein of human milk and as being quite distinct from casein. It appears to be the albumin contained in human milk which is not present to anything like the same extent in cow's milk. Some authorities regard this fact as an explanation of the failure of cow's milk to feed the human child quite satisfactorily. Clinical reports, at all events, are quoted which in face of the evidence presented entirely support this view. The most striking results are those in which diluted cow's milk failed by itself, but succeeded when a proportion of albulactin was added to it. If that is the case, then the use of albulactin marks a decided advance in artificial infant feeding. According to our examination, albulactin shows a decidedly alkaline reaction and contains: moisture, 10·40 per cent.; mineral matter, 6·0 per cent.; and albumin, 83·60 per cent.

### DIETETIC STOUT.

(PETER WALKER AND SON, PANCRAS-ROAD, LONDON, N.W.)

Analysis revealed some favourable features in this malt liquor. The practical absence of volatile acidity is particularly satisfactory and indicates a healthy condition. Moreover, the stout is "smooth" and "soft" on the palate. The malt extractives amounted to 5·81 per cent., of which 7·0 per cent. consisted of proteins. There can be little doubt, therefore, of the nourishing value of the beverage. Further examination indicated that the stout is made exclusively from malt and hops. The mineral matter contained an abundance of soluble phosphates. While the stout is decidedly nutritious, its condition is sound, and its alcoholic strength is not excessive. The amount of alcohol found was just under 5 per cent. by weight.

### (1) VAPOROLE AND (2) SOLUTION HEMISINE AND COCAINE HYDROCHLORIDE; (3) "TABLOID" PHOTOGRAPHIC CHEMICALS FOR COLOUR PHOTOGRAPHY.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

A combination of the suprarenal active principle with cocaine is obviously useful in dental practice, especially when the powerful hæmostatic is in such proportion as not to cause too much constriction of the capillary blood-vessels of the socket. The preparation is supplied (1) in the convenient "vaporole," a hermetically sealed glass bulb containing the solution sterilised, or (2) in stoppered bottles of 10 cubic centimetres capacity. (3) The photographic tabloid offer an undoubted facility to workers in colour photography, the

application of which in medical studies is well worth pursuing. We understand that the whole process of development in the production of a colour photograph, reversal, redevelopment, and intensification can be carried out with solutions of tabloid rytol, tabloid reversing compound, and tabloid colour plate intensifier. These tabloids should render considerable assistance in the production of colour photographs in skin diseases, of histological specimens, and so forth.

### GALVANIT.

(THE GALVANIT MANUFACTURING CO., 6 AND 7, GEORGE-STREET, HANOVER-SQUARE, LONDON, W.)

Galvanit, a successful plating powder, has been before the public some little time, but recently a series of powders has been introduced which are adapted to scientific and surgical purposes. The powder called "stannit," for example, affords an excellent way of renovating the surfaces of surgical instruments. A perfectly uniform silvery metal is deposited upon the steel by merely rubbing it with the moistened powder. According to Professor Sylvanus P. Thompson, in this process the particles of the finely divided electro-positive metal make innumerable contacts with the copper surface and act as so many minute anodes. These innumerable minute anodes gradually dissolve, and in dissolving set up in the liquid little local circulations of electric currents which, as they leave the liquid, throw down from the metal in solution a film upon the surface, which thus acts as a cathode and becomes plated over with the deposit. We have tried the powder on various surgical instruments with success. Special plating powders are supplied for different metallic surfaces.

### GROATLINGS.

(J. AND W. ARBUCKLE, COLTBRIDGE MILLS, EDINBURGH.)

This is oatmeal in the form of fine grains, a treatment of an admittedly valuable food which renders it dietetically very satisfactory. There can be little doubt that coarse particles are a source of irritation to many persons, while they often prevent or complicate complete cooking. The graining process is conducted also in such a manner as to preserve unimpaired the esteemed nutty flavour of high-grade oatmeal. On analysis we found the product yielded normal results; it contained, for example, 9·4 per cent. of moisture, 3·0 per cent. of mineral matter with an abundance of phosphates, and 10·4 per cent. of protein. It makes a porridge bland and smooth as milk.

### "FLANKETS."

(CHRISTOPHER WILLIAMSON, 91, EDGWARE-ROAD, LONDON, W.)

We are sure that these all-wool sheets will be appreciated by many people who feel chilled at the touch of the linen sheet in winter. The "flanket" is a decided improvement upon the flannel blanket, which is often a source of irritation to the skin. We found on examination that the flanket was pure wool. It has a smooth surface and is comfortable next to the skin. They will supply, we think, a domestic commodity which will be acceptable to many persons who feel the cold severely. They are certainly more hygienic than the flannel blanket, and while warm are not heavy.

### FORMAROSE TABLETS.

(ARTHUR H. COX AND CO., ST. MARTIN'S-PLACE, BRIGHTON.)

Formarose tablets embody an excellent formula for throat and mouth disinfection. An interesting novelty in regard to them is that in the course of preparation of the tablet a concentrated infusion of fresh flower combined with a very small quantity of genuine oil of rose is employed. The result is a pleasant and elegant antiseptic lozenge.

### CELLULOSE FILMS.

(W. MARTINDALE, 10, NEW CAVENDISH-STREET, LONDON, W.)

These films are prepared in three forms and thicknesses, known respectively as taffetas (yellow), aseptafilm (colourless), and cellafine (colourless thin). The film is a very interesting product which is perfectly transparent and analogous in appearance to gelatin sheeting. Taffetas is used as a substitute for oil silk; aseptafilm is suitable for applying direct to wounds; and cellafine is a grease-proof covering which is of service in many obvious directions. The films are not affected by alcohol, ether, or chloroform, nor by prolonged immersion in hot water, and there is no difficulty, therefore, in sterilising them. These interesting films, made of an entirely innocuous material, promise to be of distinct service in medicine.

### RUSKS.

(EMIL PAULY, 98, UPPER THAMES-STREET, LONDON, E.C.)

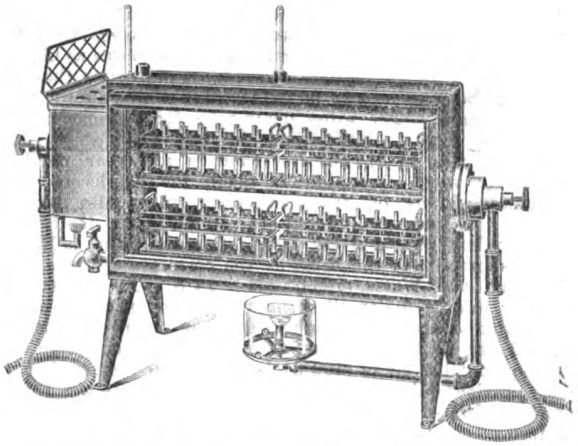
This is a well-prepared crisp rusk, having as well a good keeping quality. It is free from an excessive amount of sugar and contains butter-fat and milk protein. We found that 23·0 per cent. of the rusk was soluble in water. The fat amounted to 3·45 per cent. The rusks are digestible and nourishing. Their texture involves thorough mastication, and that is probably one good reason why the rusk is digestible.

# New Inventions.

## (1) A NEW OPSONIC INCUBATOR; AND (2) THE ANHYDRIC INCUBATOR.

THE new opsonic incubator is fitted, as shown in the accompanying illustration (Fig. 1), with Hearson's ingenious thermostat and capsule which automatically keep the temperature constant. The incubator consists of a double-sided reservoir and is provided with a glass front and back. It is intended to be used on a bench facing the light, and at the back are two grooves for the insertion of different

FIG. 1.

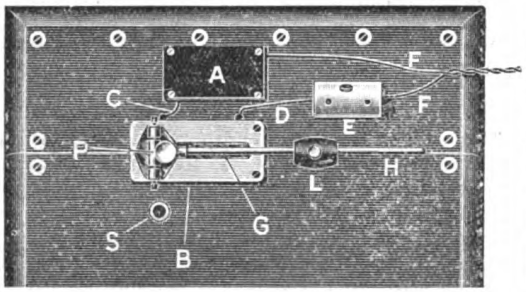


coloured glasses. For the examination of blood a red glass is used, while for toxins a blue glass is used. On the side of the apparatus is a small tank fitted also with Hearson's patent thermostat and capsule. The temperature of the tank is regulated for 56° to 60° C. for the sterilisation of liquids. It contains two perforated plates, one for ordinary test-tubes and the other for small tubes. The apparatus is very neat and compact, and lends considerable assistance in carrying out the Wassermann test.

In the anhydric electric incubator the constant temperature desired is obtained entirely by the electric current from the main. The incubator, which is of the ordinary type, is wound round with electric resistance wires covering every part of the chamber formerly occupied by the water-jacket. Directly the current is switched on there is a steady production of heat over every part of the interior surface of the chamber, increasing until the expansion of the thermostat

brings about the automatic interruption of the current. There is, of course, no heating arrangement below the incubator. The illustration (Fig. 2) shows the resistance apparatus on the top of the incubator. A is the junction-box; B, china base; C D, conductors; E, fuse-box; F, "leads" to main current; G, platinum contacts; H, lever

FIG. 2.



rod; L, lead weight; P, a milled-head screw; and S, thermometer hole. Instructions for working the incubator are sent out with each apparatus by the manufacturers, Messrs. Hearson, of 235, Regent-street, London, W. The incubator works satisfactorily and smoothly by merely switching on the current from the main, so that its convenience cannot be disputed.

## PUBLIC HEALTH AT CAPE TOWN.

THE report on the vital statistics of the city of Cape Town for 1909–10 bears no date, but appears in good time, and therefore has all the more interest. The birth-rate for Europeans here, as elsewhere, is decreasing, though not rapidly, nor in a regular ratio. For the period to which the report refers—July, 1909, to June, 1910—the ratio was 22·6 per 1000, the European population being estimated at 34,300; for the coloured population, estimated at 32,250, the ratio was 50 per 1000, this figure being also lower than the average. The illegitimate European birth-rate was as high as 9·5 per cent. of the total, a much higher proportion than has hitherto been recorded; no explanation can be afforded for this increase. The gross death-rate for Europeans was 13·23, a higher figure than in any year since 1904 (when it was 14·3), but less than in any year previous to that; when correction is made for deaths of non-residents (many of these occurring in public institutions) the rate is lowered to 10·72, but if further corrected for age and sex distribution the figure is 14·61; this is practically the same as the corrected death-rate for England and Wales (1909)—viz., 14·5. The death-rate among infants under 12 months is an index of the social condition of the population; in the year under review it was 104·2 per 1000 births, a figure slightly higher than the quinquennial average (102·8), but very much lower than in any previous quinquennium; in 1900–05 the rate was 135·1, and in 1895–1900 as much as 180 per 1000 births. The improvement is due to the improved sanitary condition of the city, and the greater attention paid to the feeding and care of young infants. A lady inspector visits and takes notes of obvious sanitary defects and faulty methods of feeding; she advises as to the preparation of food, cleaning of bottles, and so on. It is very satisfactory to find that these visits are much appreciated.

The zymotic death-rate was 1·25 per 1000 for Europeans, measles, diarrhœal diseases, and whooping-cough being the chief causes. There was a serious epidemic of measles, lasting from November to June. Dr. A. J. Anderson, the medical officer of health, believes that nearly every susceptible child took the disease; it is not yet notifiable, and is therefore not generally regarded as a serious complaint, so that precautions against cold are not taken. The number of deaths returned does not, of course, represent the true fatality of the disease, as many are certified as broncho-pneumonia. During the last three years diphtheria has been of a severe type, though not prevailing to any considerable extent. In 1909–10 there were 38 cases and nine deaths; it is noted that drains were defective in many instances; no allusion is made to milk-supplies nor to any other possible mode of spread. There were 41 cases of enteric fever in Europeans, 15, however, being introduced into Cape Town from outside; only one death occurred. Defective drains are stated to have been present in 17 cases; no other cause is suggested, and there was nothing in the shape of an outbreak. The death-rate for tuberculosis among Europeans was 1·65 per 1000, or, if corrected for non-residents, 1·45; but as the constitution of the population is such that there is a larger proportion than is normal of persons in middle life (when the death-rate is higher), if the suitable factor for correction is applied the death-rate comes out as 1·30 per 1000. There were 69 cases notified amongst Europeans, of whom 35 were clearly shown to have contracted the disease before coming to reside in Cape Town; but in addition 14 deaths from tuberculosis occurred among Europeans that had not been notified. Great care is taken in regard to isolation and disinfection; and, as far as possible, advanced cases are removed to the Old Somerset Hospital, while cases which will derive benefit are treated in chalets. Fortnightly visits are paid to notified cases. Dr. Anderson considers these visits to be of great assistance in seeing to the cleanliness and ventilation of the dwellings, the use of spit-cups, &c.; he has been "struck with the improvement that has taken place in many cases which were apparently hopeless when notified." The Free Dispensary is opened one evening in each week for the examination and treatment of persons supposed to be suffering from the disease; but adequate accommodation for advanced cases is urgently needed. Not a single case of small-pox was notified during the year.

As to general health conditions, in regard to water-supply, this is satisfactory as to its source, being derived from springs on Table Mountain. Each house is supposed to have a covered galvanised iron tank for storage, fed on the "dribble" system, but there are many defective water barrels and other makeshifts still in use as cisterns, and the provision of a constant supply is an urgent necessity. Some part of the supply is derived from a catchment area on Table Mountain, which yields a water discoloured from vegetable matter held in solution. An experimental plant has been installed to remove this objectionable constituent. The health officer states that the water as delivered to the inhabitants is remarkably pure and free from injurious matter. We should like to have seen more particulars as to the sources of supply and its chemical and biological characters, on which points it is usual to rely on the medical officer's report for information. The arrangements for milk-supply within the city are regularly inspected and kept up to the mark; but the water sources of farm premises and places outside the city are in many cases grossly polluted. Dr. Anderson considers that the time has now come when a public supply of water should be laid on to the district whence the milk is derived. Mosquitoes cause considerable annoyance within the city, and measures are being taken to endeavour to exterminate them; nothing is said as to the species that are found, or their relative abundance. Only one death occurred during the year from malaria.

The coloured population in Cape Town numbers 32,250; their death-rate was 35·28 per 1000, or 33·30 when corrected for non-residents; and their zymotic death-rate was 4·27. Measles, whooping-cough, and diphtheria prevailed to some extent, also enteric fever. Tuberculosis was the most frequent cause of death, giving a ratio of 7·00 per 1000; or, if corrected for residence and age constitution, 6·04 per 1000. Pneumonia was also fatal, as is the case with native races generally.

ASSAULT ON A MEDICAL OFFICER OF HEALTH.—At Penzance on Dec. 21st last a man was fined 5*s.*, and his wife was bound over to keep the peace for 12 months, for assaulting Mr. J. R. M. Richmond, medical officer of health of the Penwith rural district council. Evidence showed that owing to the insanitary condition of the defendants' cottage Mr. Richmond had been ordered by the magistrates to inspect the dwelling. When Mr. Richmond attempted to enter the cottage the man pushed him away, and the wife procured an axe and threatened "to cleave him" with it.

# THE LANCET.

*LONDON: SATURDAY, JANUARY 7, 1911.*

## The Promise of 1911.

WE are entering not only upon a new year, but upon a fresh decade. The twentieth century so far has done its full share in developing the natural resources of the world and in turning them to account for man's benefit: there are no signs of pause in the forward movement, or of any slackening of the attention with which the public scrutinises all that, occurring in any scientific or professional department, is proclaimed as beneficial to the community. We may anticipate that when future generations review the social history of the years 1901–10, the practical application of wireless telegraphy, the popularising of the mechanically propelled vehicle, and the attempt to overcome the difficulties and dangers of aerial navigation and of aviation will be found to rank among the most prominent feats of human ingenuity. We are not called upon to prophesy, with regard to this last, that the rivalry of the flight of birds with the aid of an engine and fixed planes will pass into a permanent improvement of human amenities; but whatever we may expect the verdict of posterity to be upon the value of the mechanical innovations, we may be sure that the fearlessness of the pioneers of aviation will never be forgotten. We have alluded to three sudden leaps forward that have occurred in mechanical construction. The onward movements in medical science may vary, or appear to vary, in pace; but they are seldom characterised by these abrupt leaps. Our progress is usually made without sensational features such as would focus the public attention. It is, on the whole, steady, and the most notable advances have the least obvious appeal to the public eye, so that we consider it to be of good promise for the future, that a more general interest in medicine appears of late to be aroused.

The year 1910 has not witnessed the exorcising of the demon Tuberculosis, because tuberculosis is not a supernatural visitation or one susceptible to the miraculous operation of a charm; but it has seen the continued efforts of science bringing us nearer to that stage of knowledge at which mastery of the disease may be hoped for, and it has witnessed the intelligence of the nation directed to the consideration of practical measures of prophylaxis and mitigation. It has seen scientific research applied with unabated zeal, and with undiminished confidence in ultimate success, to the elucidation of the problem of cancer. It has seen the great voluntary hospitals of the kingdom and of its metropolis carrying on their good work with increased efficiency, and a generous public, in spite of a period of commercial depression, of political anxiety, and of other causes which might be expected to diminish their charitable subscriptions, has supported with liberality institutions which have deserved and won its confidence. The regular subscriptions to charities have in some directions dropped off, but in other directions the money has come in. We have no doubt that the funds forthcoming in the British Islands in support of enterprises having for their object the combating of physical suffering have received a powerful stimulus from recent achievements of science, forming an illustration of the popular proverb which declares that "nothing succeeds like success." The fact that rabies can be made less deadly in countries where it is prevalent owing to the discoveries of a scientist whose beneficent work in this and other directions has had its effects in every country of the globe, and that in Great Britain the disease has been stamped out owing to precautions advised by science and undertaken by the public for its own protection, are things that the public can readily appreciate. The world has accepted at the hands of science a weapon of defence against diphtheria, and in this country the gift is now being brought within the reach of the poorest. During the past year the plague, which many medical men, as well as all laymen, have regarded as an oriental disease, extinct with us since the days of the STUARTS, has returned to shores where it was once practically endemic, to be met by science armed with the knowledge of its mode of propagation and of the practical measures to prevent the extension of its ravages. If instances needed multiplication the achievements of modern surgery might be taken as examples of that which medical men of a former generation would have regarded as almost miraculous. The surgical exploits are much admired by the public, sometimes without due discrimination, and, for this reason among others, we have sometimes suggested that the popular discussion of scientific discoveries in lay newspapers has its drawbacks. But we admit its compensating advantages. The medical profession is aware of what the popularisation of their efforts has done in the past for the cause of science, and at the opening of a new year looks forward with confidence to supplying the public with good reasons for securing public esteem.

The present year or the not distant future may see problems solved of great importance which affect the medical treatment of the poor and of the working classes, and concern, directly or indirectly, the position of a large number of members of the medical profession. The questions are intricate, and on many of them the medical profession has no settled mind, a position which we hope will be altered as discussion clears the many issues. Legislation against quackery is in the air. The medical profession, governed and to some extent protected by medical Acts of considerable antiquity, is looking forward to a day when the Legislature will better safeguard not so much the profession as the public, now exploited without hindrance by any grasping charlatan or dangerous quack who is wary enough to keep outside the provisions of the statutes referred to. An additional reason for such protection of profession and public alike should be found in the improved and extended training provided for those entering our calling. The alternative to the quack and the charlatan is now a highly instructed man who has spent some of the best years of his life, not to reckon a large sum of money, in acquiring the skill which he places at the disposal of his fellow citizens. The fuller understanding, which has certainly come about,

of the medical profession by the public leads us to hope that the difficult subject of quackery will be dealt with in a comprehensive manner. We expect no foolish monopolies.

The year that lies before us appears likely to be distinguished by political contention and uncertainty which may retard domestic legislation and the settlement of questions which the medical profession would willingly see decided. The present Administration has, however, shown itself fully alive to the importance of conserving the physical health of the people, and there is every reason to hope that some of the needed reforms, which concern the medical profession, such as those which were brought into prominence by the Reports of the Poor-law Commission, will receive serious consideration before long. Progress may also be made in other directions, such as that initiated by the passing of the Housing and Town Planning Act. We may in fact, in matters medical, congratulate ourselves upon a hopeful state of affairs and upon the prospect of a sustained forward movement in the year 1911.

## Order and Charity.

THE lecture delivered by Dr. LAURISTON E. SHAW before the Stratford Division of the British Medical Association and published in THE LANCET of Dec. 24th, 1910, p. 1813, draws attention in clear terms to the present disorder of medical charity. Dr. SHAW is not content merely with indicating the causes, immediate and remote, internal and external, of this disorder, but has a remedy to offer, and in these days an ounce of constructive suggestion is worth a ton of vague criticism. Briefly stated, his remedy is the institution of a genuinely consultative out-patient department, for which, of course, he takes out no patent, for others, we among them, have made a somewhat similar recommendation. In his proposal Dr. SHAW has regard to certain limitations necessitated by the present condition of affairs, political and social. He recognises that political influence in this country is rapidly passing from SULLA to MARIUS, so that it is important, if assistance is to be expected from Government, to propose a plan which will not interfere with any State scheme which may be brought about for providing medical attendance for the very poor. At the same time it would be unwise to place any impediment in the way of such provident schemes as at present exist or may come into operation for providing medical attendance for the moderately poor, such as provident medical dispensaries and combinations of general practitioners in public medical services. Thirdly, no scheme is likely to succeed which will damage the scientific work of the great hospitals, or alienate the sympathy of those members of the medical profession in whose hands lie the education of the students and the progressive labours of scientific research. Medical charity, associated as it always has been with medical education and medical research, must not be violently divorced from them, or the professional aid dispensed by that charity will soon become a lifeless thing. The patient, the general practitioner, and the consultant practitioner (in his capacity as such and as teacher) are the three working partners whose interests are in question, and who are to be considered and satisfied in any arrangement for the distribution of medical benefits. There is, however, a fourth partner—a sleeping partner—who does not come much into contact with the actual working of any of the schemes promulgated, but who is perhaps the most important of all. The hospital subscriber cannot be left out of consideration in any hopeful proposals for hospital reform. It is probable that he may be persuaded for a time by one or two of the working partners against the remainder, but no arrangement is likely permanently to please him that does not lead to harmonious and satisfactory relations amongst all four partners in the firm.

The present disorder is largely occasioned by the prevalent neglect of the interests of the general practitioner, who sees his position gradually, but surely, imperilled by the excessive volume and uncoördinated character of much of the medical charity distributed to-day. His assistance and approval are necessary to the successful working of a hospital, if only because he is, or should be, the channel of income to much of the consultant class. The general practitioner has somewhat lost his influence in determining the destiny of charitable donations, subscriptions, and legacies, for the organisation of great hospital funds has deprived him of the position which he once enjoyed as paramount adviser to the public in such matters, but, nevertheless, his personal influence amongst the hospital subscribers in his own neighbourhood is a power to be considered; while the operation of public medical opinion, founded upon the best traditions of the medical profession, will work against the exploiting of the general practitioner by misdirected benevolence. Some are inclined to blame the philanthropist for the excess of his charity, for the want of coördination that it shows, and for the lack of discrimination in its incidence. It is not necessarily the philanthropist who is to be blamed when philanthropic schemes go wrong. As Dr. SHAW has so wisely remarked, "Sympathy with pain and suffering is a quality none could see lessened one iota without fear for the future of our race." When alms are given in excess of necessity, when judgment is wanting in the selection of beneficiaries, when philanthropists obstruct one another in their eagerness to relieve distress, charity is abused and fails of its purpose, but it is the administrators who are at fault. These things are now being generally if tardily appreciated. In conformity with the spirit of the times endeavours are being made in the management of medical charity whereby the gifts of the charitable may reach only worthy recipients, and sound hopes may be entertained that the abuses which have flourished for years out of promiscuous and ill-considered giving will be prevented, as their causes are better understood.

More than the volume of medical charity, the muddle of it is responsible for much of its present ineffectiveness, and the want of coöperation between the two branches of the medical profession is a truly vexatious factor in the trouble. There is no doubt that the interests of the general practitioner and those of the consultant do not lead both to regard the out-patient question with the same eye. The public are said to be ill-informed and ignorant

when they imagine that members of hospital staffs are remunerated for their services, but the eagerness with which hospital appointments are sought after, and the strenuous competition which prevails to secure any that are vacant, must abolish the idea that a hospital physician or surgeon considers himself to be wholly unrewarded by filling these honorary posts. Services which are voluntary, even if indirectly remunerated, possess certain features which enable those who give them to obtain consideration and respect, and the members of the medical staffs of our great charities possess great power which can be exerted for the restriction of the volume and the control of the incidence of medical charity in London and other large towns where similar evils exist. Often the influence of the medical staffs is vigorously employed in sifting their out-patient departments; but such action is apt to be individual and capricious. Coöperation between the general practitioner and the honorary medical staff of the hospitals seems necessary to bring about a just reform in hospital administration, and the consultative out-patient department, with the abolition of subscribers' letters, together with the introduction of a rule whereby admittance to a hospital shall depend on the production of a medical certificate of suitability, are proposals which deserve serious attention. And we may feel all the more certain that they will receive them because of the wise move just made by King Edward's Hospital Fund for London, which has instituted a committee to consider and report upon the whole subject of hospital out-patient practice.

## Anarchism and the Criminal.

THE interest which has been aroused by the Houndsditch murders and their later developments is doubtless due chiefly to the startling contrast which these crimes in their reckless ferocity present, not only to the ordered habits of civilised life, but even to the usual methods of the most violent and most criminal members of the community in which we live. Such outbursts of savagery may moderate our excessive confidence in the stability of our civilisation by reminding us of the strength and inveteracy of the passions which that civilisation has to curb, and may make us inquire with some anxiety into the causes which have seemed of recent years to be weakening the force and authority of its salutary restraints. It is true that these particular crimes have been perpetrated by individuals belonging to a different race and civilisation, where the political institutions are of a more primitive type, and where order and the sanctions of government rest on less assured foundations than in this country. And this consideration may certainly be admitted to justify the belief that there should be little risk of the anti-social elements in our own community taking immediate example from the miscreants of Houndsditch, while the extraordinary sequel of Tuesday last has furnished an object-lesson, terrible enough, whether necessary or not, to check the outlaws of society in their desperate schemes. But it would be rash to assume on these grounds that we can have any permanent immunity from the conditions which in other countries are producing these peculiarly dangerous manifestations of criminality, or that the development of such conditions amongst us will not bring about similar results. And therefore it behoves us to examine with some care the tendencies and characteristics of this modern type of delinquency which has been so forcibly brought under our notice by the Houndsditch criminals.

One of the most striking features of this organised criminality, and a feature which has peculiarly impressed the popular imagination, is manifested not only in the application to criminal ends of the latest resources of experimental science, but also, it would appear, in the adoption by the ultra-modern criminal of the speculative doctrines of anarchism. The scientific burglar, if we may judge from recent events, is beginning to include amongst his impedimenta, as well as the oxyhydrogen blow-pipe and the latest and most costly explosives, a selection of economic and political literature of a similarly modern and destructive character. If this fact is duly established—and there is some evidence of its reality, at all events amongst continental criminals—it suggests some interesting considerations as to the relation between such subversive doctrines and the tendency to crime. Of course, the rough-and-ready explanation is to attribute the criminal conduct to the anarchist theory, but a very little reflection is sufficient to show the inadequacy of any such view. The criminals who hold anarchist opinions are still too few, and the theoretical anarchists who abstain from actual crime are too numerous to give much support to this interpretation of the facts. But though it is probably true that the alliance of the new anti-social doctrines with the old anti-social tendencies is becoming less rare, we shall do well to remember how large an element of the merely fortuitous there is likely to be in their association. The criminal, if he has any turn for speculative thought and feels any need to fit himself with a philosophy appropriate to his career, is apt, like the rest of the world, to let his opinions be coloured very largely by the mental atmosphere of his time. He will lean naturally to the theories of the day that accord with and justify his anti-social tendencies, and these theories may thus come to be regarded as the cause of conduct which in reality is simply the expression of a vicious disposition. Criminals of this type may accordingly profess anarchist opinions, but they are not criminals because of their anarchism; they are anarchists because they are criminals, and because anarchism amongst the doctrines of the hour is that which best harmonises with their parasitic and destructive inclinations. In another age they would have espoused with equal zeal doctrines of a diametrically opposite intellectual tendency but offering a similar outlet for impulses of violence; the *apache* of to-day, who has *Vive l'anarchie* tattooed over his heart and who is eager to do murder in the cause of the social revolution, would have been no less ardent in his zeal for religion and no less eager to imbrue his hands in the blood of heretics had he lived in the Paris of the sixteenth instead of the Paris of the twentieth century. The times and the ideas have changed, but the temper and the passions are the same; and just as the lunatics of our epoch are tormented by wireless telegraphy and Roentgen rays, and are no longer possessed by devils or plagued by malignant imps, so the native and instinctive barbarians of our modern civilisation do

not now profess to be inspired by religious or patriotic ideals, but may justify their lust for violence on the plea of their intense humanitarian aspirations and the ardour of their zeal for social justice. But with us the pseudo-anarchist criminal is still an uncommon type. So far as the average criminal troubles himself about social and political doctrines he is ordinarily very little inclined to extreme views; he is, on the contrary, at all events in this country, strongly conservative in his tastes and opinions, and is much more prone to conventionality than to innovation. Amongst foreign criminals, though conservatism is also the rule, revolutionary views appear to be less exceptional, and PERRIER in his interesting study of prison life ("Les Criminels," Paris, 1900) is able to quote extensively from the anarchist effusions of a number of French criminals; the passages he cites, however, are often more suggestive of deliberate parody than of the spirit of strenuous conviction. It is, however, to be noted as a very suggestive fact that the tendency to adopt these subversive views in a quite serious spirit would appear to be much more pronounced amongst the younger criminals; and on these juvenile delinquents anarchist doctrines seem to exercise a real and very deplorable influence which, according to many competent judges, has had a large part in giving to the juvenile crime of the great continental cities that character of exceptional violence and ferocity which it has so often manifested of late years. No such influence appears to be traceable, at all events as yet, in this country, where, of course, the gospel of anarchism has, fortunately, found but few preachers and few disciples. But the evidence of its effects elsewhere may well warrant some anxiety as to the response which its doctrines may one day elicit from the human material which we continue to breed from degenerate stocks in the slum environment of our towns.

The interest of the question lies, then, rather in the future than in the present. So far there is little reason to think that anarchist ideas have had much real influence on the amount or character of criminality, nor does it appear that we need attach any great significance in this connexion to the fact that some few criminals affect to share the principles of "the party of action." On the other hand, it is impossible to deny that the wider dissemination of these doctrines is likely to have in the future a very real and potent influence in stimulating criminal instincts, and this the more because the conditions of the modern world which have helped to propagate these ideas tend in so many ways to create a social atmosphere favourable to crime. That traditional and unquestioning acceptance of their essential justice, on which law and social institutions depend for so much of their authority, ceases to be possible where laws inspired by widely differing conceptions of justice and institutions, embodying widely differing social ideals, are brought into comparison and conflict, and hence there results a weakening of their restraining influence on the unstable and undisciplined minds of the community. This is in large part the explanation of the well-known fact that crime is specially prevalent at the points of contact of different civilisations; the standard of conduct is generally lower amongst immigrants than amongst native-born inhabitants, it is lower in seaports than in inland towns, and lower on the frontiers of a State than in the interior. And the whole tendency of our age is, of course, to facilitate this interaction of differing and therefore mutually solvent ideals; the religious and political institutions, the ethical standards, the literatures of each country are becoming familiar to all, and this wider outlook tends to produce a detached and critical attitude towards traditional customs and beliefs. A too rapid development of cosmopolitanism thus involves a certain danger of diffusing through all classes a spirit of moral scepticism which impels the weak and the vicious to crime, while at the same time it weakens the confidence of society in its own power and authority and thus begets a feeling of flabby sentimentalism towards the enemies of the social order. These conditions are obviously favourable for the propagation of anarchist theories, and for their speedy transference to the sphere of lawless action; and it is as a warning of this grave danger in the near future, rather than as an evidence of its actual appearance in the present, that we may note with some misgiving the recent signs of an association between anarchism and the more sinister forms of organised crime. Possibly it was with some such feeling as this that the appalling object-lesson has been given of an attack by a large and combined force of police and military upon a house in the metropolis, culminating in the burning of the house with the criminals secreted therein.

# Annotations.

"Ne quid nimis."

## THE NEW YEAR HONOURS.

THE opening of the new year has again been marked by the issue of a list of honours which, though it may be characterised as political for the most part, contains the names of several men distinguished in the world of science. The medical profession receives one baronetcy and six knighthoods, as well as a fair amount of minor honours. The public career of the Right Hon. Leander Starr Jameson, who has been made a baronet, needs no recapitulation from us. The work of his maturer life has not been medical, but we may confidently ascribe his success, and that in no small measure, to the rigorous training exacted by the medical profession from those who would serve her well. Among those who have received knighthood is Dr. Horatio Bryan Donkin, medical adviser to the Prison Commission and Director of Convict Prisons. As a member of the Royal Commission on the Care and Control of the Feeble-minded he did much useful work, while he also assisted the Departmental Committee on the Inebriates Acts and the Treatment of Inebriety. Mr. Frederic S. Eve, another of the new knights, is senior surgeon to the London Hospital and a consulting surgeon to the Evelina Hospital. He is a member of the Council and of the Court of Examiners of the Royal College of Surgeons of England, and his work as a clinician and a pathologist is well known to all our readers. Dr. David Ferrier, who has also received a knighthood, has to his credit original researches in neurology which have been

recognised and appreciated in all parts of the civilised world. He is consulting physician and emeritus professor of neuropathology at King's College Hospital and consulting physician to the National Hospital for Paralysis. Dr. George Newman, chief medical officer to the Board of Education, is the recipient of a well-merited knighthood. The best testimonial to the work which he has done is his suggestive report on the inspection of school children to the Board of Education for the year 1909, which was presented to Parliament at the end of last November. He is a member of the Board of Hygiene Studies at the University of London, a lecturer in public health at St. Bartholomew's Hospital, and is the author of some important publications on public health and bacteriology. Dr. Joseph Michael Redmond, an ex-President of the Royal College of Physicians of Ireland, who has written much and ably on medicine, has been made a knight. A knighthood has also been conferred upon Lieutenant-Colonel David Semple of the Royal Army Medical Corps, Director of the Central Research Institute at Kasauli, whose work on bacterial vaccines and serum-therapy generally has thus received a well-earned official recognition. The Kaisar-i-Hind gold medal has been conferred upon Lieutenant-Colonel Henry Smith of the Indian Medical Service, civil surgeon of Amritsar, and on Major Thomas Walter Irvine of the Indian Medical Service, late residency surgeon at Mewar. Sir John Reynolds Roberts, well known in the textile trade, who has been knighted, has for a long time associated himself keenly with philanthropic and charitable institutions, having presented the Woodford Jubilee Hospital to Woodford, and bountifully supported among other charitable institutions the West Ham Hospital and the Canning Town Hospital for Women. To each of these gentlemen in the name of the profession we offer our hearty congratulations.

## ARCHÆOLOGY AND ANATOMY.

THERE has recently been published by the National Press of the Egyptian Government a lengthy report containing the findings of the first season's work of the Archæological Survey of Nubia. The present work constitutes Part II. of the first annual report, and it consists of one volume of descriptive text and one volume of plates illustrating representatives of the vast collection of bodies examined and some of the more important features of objects of special interest. The field-work of which these volumes are the outcome was carried on during the winter of 1907–08 in the tract of Lower Nubia lying between Shellal to the north and Khor Demhit to the south, and it embraced an examination of burial-grounds upon both banks of the Nile. The object of the expedition was purely utilitarian; there was no attractive glamour of buried treasure, no influence of the spell of the ancient dead, but only a systematic and sober recording of the conditions found in a vast number of burials which would inevitably have been lost for ever in the flooding of the Nubian Nile valley by the raised water-head of the Aswan dam. The rebuilding of the barrage, from its original height of 105 metres above sea level to its new height of 115 metres, meant that a great head of water, destined for the supply of the crops of Egypt, would be held up behind the dam in Nubia. The Nile in Nubia, when all the work is completed, will become a great reservoir of water the limits of which will far outstrip the present margins of the river banks. Owing to the geographical conditions of the Nubian Nile valley this raising of the water level must necessarily destroy practically all traces of the ancient peoples who dwelt upon the river-side, for the narrow strip of water and the sparse ribbon of foreshore provide the only habitable spot in all the country, and here, ever since man inhabited Nubia, succeeding generations have lived and died and been buried. All, save this fertile strip of river bank, is desert, and so along the margins of the river all the populations of Nubia during all the ages have had their home and their burial-place. The flooding of this strip would, therefore, destroy the one site in Nubia in which evidences of the history of the country and its peoples could be found. Unfortunately, much had already been destroyed by the original building of the dam, for above the actual water-line is an area of dampness which is immediately destructive to these ancient burials. The Egyptian Government realised the importance of rescuing the unspoiled burials from the rising water, and the Survey Department organised an expedition consisting of surveyors, archæologists, and anatomists for thoroughly examining all the burial-grounds situated within the danger zone of the new Nile level. The inclusion of anatomists in the expedition—an innovation in the methods of Egyptology—was due to the wise foresight of Captain H. G. Lyons, then Director-General of the Survey Department, and his insistence on the necessity of skilled examination of the human remains receives ample justification in the appearance of the present volume. For many reasons the site of the first season's work was likely to prove a rich field for the anthropologist. The tract of country under examination had been, through all the periods of Egyptian history, a frontier line—the line where black and white met, and where in times of peace they mingled their races by intermarriage, and in times of war killed each other in border raids, or inflicted wounds which show to-day the obvious evidences of their presence. Both for the study of the race question, and for the examination of a large series of wounds and fractures, the district around the Pillars of Konosso—the gateway to the Kingdom of the South—was a favourable site. A vast amount of work was done; no less than 2000 bodies lay exposed at one time in one single cemetery, and many of these bodies were so perfect that their examination took more the form of a post-mortem inquiry than a mere osteological inventory. Burial-places of all periods were excavated at scattered sites for a distance of some 30 miles along both banks of the Nile, and from all these cemeteries—embracing burials dating from some 3000 years B.C. to about the fifth century of the Christian era—abundant material came into the hands of the anatomists. The material was dealt with in a systematic way both at the graveside and afterwards in Cairo and London, and the questions of the race characters of the bodies met with, their age and sex, their anatomical anomalies, and their pathological manifestations are fully discussed in the report. Special attention was also paid to the state of preservation of the body and the agencies—natural or artificial—by which it was "mummified." It was in this particular form of inquiry that such an expedition was likely to furnish material of the highest value to the archæologist, for the skilled anatomical examination of correctly dated material is the method most likely to solve the problems connected with the many curious burial customs of the ancient Egyptians. It must be owned that the findings of the experts engaged in this survey are apt to be somewhat of a disappointment to those who love to wrap everything connected with ancient Egypt in a shroud of mystery and ritual. It was, however, almost inevitable that it should be so. The survey was the outcome of purely utilitarian motives; it was endowed with Government funds and carried out by specialists. It had no interested public to supply with romantic details, no museum to reap its dividend of pots and beads, and no delusions of the mysticism of ancient Egypt to be catered for by the finding of the evidences of grotesque ritual. Some of the glamour may fall from the ideals concerning mummification when it is learned that the extraordinary carelessness of the embalmers,

and their makeshift resources for repairing very badly decomposed bodies, account for most of the curious conditions to which far more picturesque causes have been assigned. It may seem cold and unromantic to learn that the pre-dynastic Egyptian was preserved by the hot sand of his shallow grave, and not by artificial embalming at all; and that his disordered bones are the results of the visits of plunderers in search of his buried pots and beads, and are not the outcome of fantastic cannibalism or quaint ceremony. But, after all, the science of Egyptology will not lose by the exchange of some of its cherished romances for the matter of fact and truer findings of this more exact investigation. It is not only the Egyptologist who may find interest in this report, for much of its matter appeals to the pathologist and the surgeon, and still more to the anthropologist and anatomist.

## THEODOR SCHWANN.[1]

ON Dec. 7th, 1810, there was born at the old city of Neuss, on the left bank of the Rhine, Theodor Schwann, whose name is imperishably written in the history of biology as the founder of the cellular conception of living organisms—a conception which, developed as it was later by Virchow, has done so much to advance our knowledge of living organisms both in health and disease. Schwann studied in Bonn, Würzburg, and Berlin. At the last-mentioned place he came under the influence of Johannes Müller, and he was afterwards for five years assistant in the Berlin Anatomical Institute. During this time he was very closely associated with Müller and with Jacob Henle, and also during part of the time with Matthias Jacob Schleiden. His first original work was a thesis for his doctorate on the subject of the respiration of the developing chick within the egg—a research which was carried out at Müller's suggestion. The five years spent at Berlin proved remarkably fertile in research. Schwann investigated the chemistry of gastric digestion, discovering pepsin and its ferment action. He then carried out researches into the phenomena of fermentation and putrefaction. He demonstrated that fermentation and putrefaction were vital manifestations of lowly vegetable organisms and that "spontaneous generation" was not to be accepted. It is worthy of note that this achievement of Schwann has always been credited to him, while his anticipation of certain of Pasteur's work has been overlooked or forgotten. Researches on the power of contraction of muscle fibres, on the elastic tissue of the arterial walls and other organs followed. He studied the structure of striated and non-striated muscle, and also that of nerve fibres, as the sheath which is called after him still serves to recall. His greatest work was, however, the book published in March, 1839, on "Microscopical Researches into the Agreement in the Structure and Growth of Animals and Plants," an octavo volume of 270 pages, with four copper plates. In 1839 he was called to the Catholic University of Louvain to fill the chair left vacant by the early death of K. J. Windischmann. Afterwards he was called to the University of Liége, and for 40 years he worked in Belgium, though during this period only one scientific work of any magnitude was published by him, as he appears to have devoted his time to the teaching of anatomy, physiology, and comparative anatomy. He died on Jan. 11th, 1882, while on a visit to his brother at Cologne. Schwann's great work in regard to the cellular conception of animal tissues is often wrongly interpreted. It is usually stated that Schleiden discovered plant cells and Schwann those of animal tissues. Certain cell forms had been described before either of these investigators brought forward their results. Müller had described the cells of the notochord and of cartilage, and Henle the epithelial cells on free surfaces. Schwann multiplied these instances and then elaborated Schleiden's view of vegetable cells developed around the nucleus to a general morphological conception of the cellular structure of the whole animal organism. He also enlarged and modified the conception of the cell, and recognised the importance of the nucleus as an essential in its structure. The organism as a whole was thus to be regarded as an aggregate of morphologically similar and equivalent cells. It was therefore no longer possible to speak of a basic vital force within the organism, and Schwann's work gave the final blow to the theory of vitalism. During the decade after the publication of his book the researches of Purkinje, Kölliker, and Remak established the general truth of Schwann's view, while bringing to light fresh facts requiring modification in the conception of cellular structure. The fundamental nature of the cell in biology is now so elementary a fact, and the study of cytology has advanced to such a degree, that it is a little difficult to realise that its discovery is so comparatively modern. The centenary of Schwann's birth should be of interest to all who have studied the history of medicine, for his work was truly epoch-marking.

## SHUTTLE-KISSING.

THOSE of our readers who can carry their minds back to the literature of childhood will remember the story told by the Brothers Grimm in their collection of folk tales concerning the three ugly fairy godmothers. One of these is described as having the appearance of suffering from what would now be known as acromegaly, and when asked why her under lip was so large she replied, "From licking the thread." Weaving is one of the industrial processes which have not changed except in a few details from the prehistoric times of the first weavers, and as a proof of this we note that an acute controversy is going on in the north of England textile districts as to certain diseases arising from what is known as "shuttle-kissing." This practice is due to the fact that the end of the weft thread has to be passed through a hole in the side of the shuttle, exactly as an ordinary sewing thread is passed through the eye of a needle, and the manner of doing this is for the weaver to apply his lips to the hole and in that way to suck the end of the thread through. This sucking is sometimes done by the weaver himself and sometimes by his "tenter," or assistant. It is obvious that in case either of the operatives is suffering from tuberculosis or possibly some other infectious disease, such infection may easily be conveyed by the medium of the shuttle from the one to the other. More than this, the yarn as wound on the bobbin which rests in the shuttle is covered with fluff, which accumulates in the eye of the shuttle and is inspired when the end of the thread is sucked through, thus setting up pulmonary irritation; and in addition to the irritation caused by the fluff the weft is stated to be treated with china clay and sizing, the latter containing poisonous substances, and particles of both are inhaled in the same way. In the case of coloured fabrics the dyes are an additional source of danger. At first sight it seems as though there should be no difficulty in applying some mechanical contrivance for making the end of the thread pass through the eye, but in alterations in any industrial mechanical process there are two factors which must be taken into account: one, the opposition of the masters, and two, the opposition of the workers. Anything which necessitates increased expenditure or impedes the

rapidity of the process has a tendency to lessen production and so to decrease wages, and such are the difficulties which stand in the way of alteration. Apparently, however, two Preston inventors—Dr. H. A. Murphy of Fulwood and Mr. J. T. Simpson, the engineer of the Preston tramways—have brought out a machine which obviates the sucking of the end of yarn by the mouth. A detailed description of this machine is not before us, but we gather from an article in the *Cotton Factory Times* of Dec. 23rd, 1910, that it is a pneumatic sucker to which the eye of the shuttle can be applied. A representative of the journal in question saw the machine tried "about eight times and it acted perfectly upon seven occasions." Here, then, may possibly be the solution of the problem. If the use of this machine, after its virtues have been confirmed, were made compulsory in all mills within a reasonable time-limit—say, two years (for we learn that that period is the life of a shuttle)—supposing that any alteration in the present style of shuttle had to be made, neither masters nor workmen could complain of any serious grievance, if, indeed, of any at all. The initial cost of setting up the apparatus would not, we understand, be heavy, and it is asserted that it does not in any way lessen the rapidity of production.

## THE BACTERIOLOGICAL STANDARDISATION OF DISINFECTANTS.

IN the January number of the *Journal of Infectious Diseases* two members of the United States Public Health and Marine Hospital Service, Dr. John F. Anderson and Dr. Thomas B. McClintic, describe "a method for the bacteriological standardisation of disinfectants," a method they recommend on the ground that "there is no question but that great fraud is practised in the exploitation of many of the so-called disinfectants that are offered for sale upon the market and are constantly being used by the credulous public. ..... Even physicians and health officers are frequently imposed upon by the manufacturers or vendors of so-called disinfectants or germicides." As the result of experience of the various methods of testing antiseptics, they, as others who have worked at this subject, are not satisfied wholly with the Rideal-Walker method, which was designed to meet the need of standardisation, even when used under proper conditions as to temperature, organisms, media, &c., as only approximately constant results are obtained by different workers familiar with the technique, considerable dexterity, which can only be obtained by practice, being necessary to obtain these results. They point out that far too great latitude is given in so far that the operator, they believe, can arbitrarily select the result that will most advantageously suit the purpose of the experiment, and this without in any way departing from a strictly honest statement of the results. These observers approve of certain modifications made by THE LANCET Commission, and state that "the Lancet method, on the whole, seems to be a distinct advance over the Rideal-Walker, but, nevertheless, it appears to have certain rather serious faults." One of these faults, the lack of a standard scale for making dilutions, has already been corrected in practice. It was, indeed, an obvious fault as soon as the whole of the material collected by the Commission was considered. The second fault is the use of the bacillus coli communis as a test organism involving the use of special media for subcultures. They object also to the use of special apparatus, particularly the spoons, and recommend the use of pipettes graduated in tenths of a cubic centimetre. Those who have used the spoons and special apparatus are satisfied that with very little practice quantities as accurately measured as those to be obtained with a pipette so graduated can be obtained. However, that is a matter of minor importance, and we are glad to find this question of standardisation being taken up with such energy and by such competent workers. The conclusions of these workers are interesting: "However, notwithstanding the objections noted, we believe the Lancet method to be a distinct improvement over any other that has been proposed up to this time, and that with it constant results can be obtained by different workers. After doing considerable work with both the Rideal-Walker and the Lancet method, we came to the conclusion that, on account of the great variation in results that may be obtained with the former method, it was not a method to advise for the examination of disinfectants. While consistent results can be obtained with the Lancet method, we believe, on account of the objections we have stated in the discussion of that method, that this method can be so modified as to greatly increase its usefulness. With this object in view, we have taken up in detail each step and factor concerned in the successful carrying out of the test, and propose the following method, to be described later for the determination of the germicidal efficiency of disinfectants as compared with pure phenol. In proposing this method we desire to make full acknowledgment of our use of the Rideal-Walker and the Lancet methods, especially the latter, as a basis for our work." The factors involved in the examination of disinfectants by these observers are the following: A 24-hour culture of bacillus coli is used; the experiments are always carried out at a temperature of 20° C.; the proportion of culture to disinfectant is 0·1 cubic centimetre of culture to 5 cubic centimetres of disinfectant; the amount of inoculation into subculture tubes is measured by loops instead of by spoons; the medium for subculture is prepared from beef extract according to the American standard and has a reaction of + 1·5, the titration being carried to a point where the pink colour is distinctly perceptible; instead of the wheel a block containing four or six grooves is used. Other minor details are given, including a table of dilutions. Finally they carry out experiments from 2½ to 15 minutes, and state that in determining the co-efficient "after a large number of experiments we have concluded that the method employed by the Lancet Commission, with certain modifications, is the best one for determining the co-efficient—i.e., the mean between the strength and time co-efficients." The whole question has been approached in a very fair and open-minded manner and we welcome the criticisms of our work.

## WORKMEN'S COMPENSATION.

A THOUGHTFUL and suggestive article on the medical aspect of workmen's compensation was published in the *Times* of Dec. 29th, 1910. It is obviously the outcome of a wide experience of this difficult problem, and is well worth careful consideration. The writer maintains that while the principle of the compensation of workmen for accidents is now too firmly established to permit of any change except in the way of further extension, the matter cannot long continue in its present developmental stage. He proceeds to point out a number of directions in which improvement is possible both from the standpoint of the employer and of the workman. He affirms that the medical question is the key to the whole subject, a view from which there would be few to dissent. He then discusses four points which he regards as essential to the proper management of compensation cases—viz., efficient diagnosis, treatment which should be adequate and continuous, the provision of certain accessories of treatment which the workman may be unable to secure, and a mechanism for dealing with permanent or chronic cases. In regard to diagnosis, the suggestion is made that the injured man should be examined by a well-trained surgeon or at a hospital as soon as possible, and that certificates of his state should be obtainable both by the employer and himself. It is probable that this would prevent many doubtful

claims, and that it would exclude many cases of gross disease present at the time of the accident which under the present system are often made the subject of claims as resulting from the accident. The writer of the article is very insistent in urging the importance of immediate treatment, since he believes that many cases of comparatively trifling injury are greatly prolonged owing to defective treatment from ignorance, carelessness, semi-starvation, or even from deliberate neglect of treatment in order to secure greater compensation. He is of opinion that if the employer were compelled to provide efficient treatment for injured employees, and they were equally compelled to submit to it, there would be a decided diminution in the sums paid for compensation. The provision of accessories of treatment, such as apparatus, change of air, and good feeding, it is possible might be met by the establishment of some special fund. A useful suggestion is also made in regard to the chronic or permanently damaged cases—namely, that operative and other treatment should be made available if this is likely to lessen or remove the disability from which the injured man suffers. Lastly, it is urged that the crippled workman should be educated and trained so as to utilise his remaining faculties to some useful and productive purpose, so that he may again become partly or wholly self-supporting. The writer of the article does not claim that his suggestions are yet necessarily within the realm of practical politics, but they are certainly well worth discussion. There can be no doubt that the present system is far from satisfactory, that it tends to encourage malingering, and by its tardy methods is a fruitful cause of neurasthenia and of what has been euphemistically called ergophobia. In any modification it is only fair that the position of the employer should be taken into consideration as well as that of the workman, and the suggestion to which brief reference is made in the article under consideration, that the workman might also contribute to an insurance fund, is one which ought to be carefully weighed, more especially if the employer is made responsible for treatment as well as for compensation.

## "THE CHEMISTRY, PHYSIOLOGY, AND ÆSTHETICS OF A CUP OF TEA."

UNDER the above title we publish this week a special article which throws a new light, we think, upon the chemistry of tea. In an experimental inquiry which has occupied the attention of our Laboratory Commissioners for some months an interesting relationship appears to exist between the chemistry of the cup of tea and the views of the expert taster in regard to the quality of the tea used in making the infusion. Until now chemical analysis of tea has been directed to a mere determination of the amount of caffeine and tannin present in the tea, without regard to the question of their probable existence in a state of combination. The work in our laboratory shows that a strong affinity exists between caffeine and tannin, and that probably the good tea, classed as such by the expert taster, is good because the caffeine and tannin occur together as a definite neutral compound, practically neither caffeine nor tannin being present in the free state. On the other hand, the cheaper commoner classes of tea, according to the expert's category, did not in the experiments we record show evidence of this equilibrium being preserved between the two substances, one or the other being in excess. In the common tea it appears probable that the bitterness of free caffeine is evident to the taster's palate, or the astringency of the free tannin, as the case may be. The good tea is classed as such because there is a definite balance of the two constituents, which, when present in certain proportions which satisfy the requirements of chemical affinity, prove satisfactory to the palate. The probability is that this balance is also of physiological importance, since free caffeine is a poison and free tannin an astringent. Tannin is well known to form insoluble compounds with alkaloids, of which caffeine is one, and it is conceivable that in tea the tannin favourably modifies the effect of this alkaloid. Caffeine in its turn practically negatives the astringent action of the tannin; caffeine tannate, at any rate, is useless for the purposes of an astringent. It would therefore appear that when the taster decides upon the quality of a sample (apart altogether from its flavour) he is guided largely by the fact that in a good tea the caffeine and tannin are present in proportions which mutually extinguish the bad qualities of each other, and these bad qualities refer not only to taste but to physiological effect.

## THE MEDICAL LANGUAGE OF THE THIRD GOSPEL.

THERE may be doubt as to the authorship of the Third Gospel—for what limits can be put to the scepticism of the "higher critic," especially if he be a German?—but there can be none at all as to the medical language that gives character to its style. The great exegetes of the eighteenth century, Bengel and Wetstein, were convinced that only a physician, or one trained for the profession, could have written it, and that conviction gained in strength till 1882, when Dr. Hobart of Dublin collected and reinforced the evidence in a special treatise, which would have been still more convincing had he, in citing his authorities, used the recensions of Littré and Ermerins, instead of the uncritical text of Kühn. Since then "the question has increased rather than diminished in interest," to quote from a treatise in which it has just been re-discussed,[1] and settled on the traditional lines; settled, moreover, in terms not less emphatic than those of the great German theologian Dr. Harnack: "I subscribe to the words of Zahn [an equally sound authority] that Hobart has proved for everyone, for whom anything can be proved, that the author [of the Third Gospel] was a man acquainted with the technical language of Greek medicine—in fact, a Greek physician." And what is true of the Third Gospel is also true of the Acts, written, as this latter book undoubtedly was, by the same hand. In the "We" sections Dr. Knowling finds, with Dr. Harnack, the same medical language as in the rest of the Acts. Let us take the famous passage (xxviii., 8–10): "And it was so that the father of Publius lay sick of fever and dysentery; unto whom Paul entered in and prayed and laying his hands on him healed him (*ἰάσατο*). And when this was done, the rest also which had diseases in the island came and were cured, who also honoured *us* with many honours." Two points are noteworthy in this passage, first, as indicated by Sir W. M. Ramsay, the word "cured" should be replaced by "received medical treatment" (*ἐθεραπεύοντο*), the latter Greek word being in contrast to the former (*ἰάσατο*) and in keeping with the careful use of medical terms in the passage; second, the contrast between St. Paul's healing power and the physician's modest description of his own medical attention to his numerous patients from all parts of the island justifies the same scholar, with Dr. Harnack, Dr. Zahn, and Dr. Knowling, in rejecting the supposition that only prayer, and not professional treatment as a means of healing, was employed. Dr. Knowling discusses many other points as to the language of the Third Gospel, the author of which, as also of Acts, he holds to have been

[1] Messianic Interpretation and Other Studies. By R. J. Knowling, D.D. London: Society for Promoting Christian Knowledge. 1 vol. 1910. Price 3s.

incontestably St. Luke. Replying to the recent criticism of Dr. Clemen, an able German theologian, that "a Greek physician would not have been likely to describe Herod Agrippa as being 'eaten of worms,'" he reinforces the traditional view by the high authority of Professor Macalister, who maintains that the disease in question, as affecting Herod Agrippa, "was a sudden and fatal seizure of some abdominal complaint, accompanied with intense agony and in some way connected with worms," while Sir J. Risdon Bennett surmised that it was acute peritonitis due to perforation of the bowel by a worm—"a rare but not impossible condition." Of these two interpretations Dr. Knowling rightly attaches more weight to that of the Cambridge anatomist, who further points out that σκωληκόβρωτος (eaten of worms) is found in Theophrastus, and that in ancient times such cases as that of Antiochus Epiphanes (II. Maccabees ix., 9) were common enough when injuries were neglected, a view supported by reference to Josephus (Ant. xvii., 6, 5). Another interesting comment of Dr. Knowling is that the "first aid" applied by the Good Samaritan to the man maltreated by brigands was practice quite in keeping with the therapeutics of the first and second centuries, to which he might have added that the "pouring on" (not, as mistranslated in the Authorised Version, "pouring in") of oil and wine after the bandage had been applied was *motivé* by the need of keeping the bandage from stiffening (hence the oil) and of stimulating the anæmic parts (hence the wine). In fact, as indicated by the late Dean Alford, a paste, mainly compounded of these two ingredients, was in medical use in the second century. Dr. Knowling's essay is an able and scholarly vindication of what few but those devoid of what William James calls the "will to believe" will now venture to gainsay—that to a practising physician in the mercantile marine of the Levant, whose name was Luke, must be ascribed the Third Gospel, which, according to Renan, is the loveliest book ever written, and also of the Acts, which Sir W. M. Ramsay esteems for its historical merit as in every sense a masterpiece.

## OCULAR PARALYSIS IN INTRACRANIAL TUMOUR.

IT has long been recognised that in cases of intracranial tumour weakness of one or both sixth nerves—sometimes even of the third pair—may be present in cases in which there is no reason to suppose that these nerves are directly involved in the growth. The usual explanation that has been offered is that the sixth nerves, on account of their long course and exposed position, are particularly liable to have their functions interfered with either by pressure against the bone or by œdema. The same explanation would be applicable to interference with the functions of the third pair, only in such cases a greater degree of pressure would have to be assumed than is necessary to induce interference with the functions of the sixth nerves. Collier has suggested that the antero-posterior course of the sixth nerves may render them more vulnerable by the pushing back of the brain stem, which is shown in so many cases by the protrusion of the medulla, and even by part of the cerebellum, through the foramen magnum, when the intracranial pressure has been excessive. In the last number of *Brain* Dr. Harvey Cushing makes a valuable and suggestive contribution to the elucidation of this point, and as a result of a series of anatomical and pathological studies he submits the view that in certain cases at least the interference with the function of the sixth nerves, especially in cases of intracranial tumour, may be due to strangulation of these nerves by transverse branches of the basilar artery. In support of this view he finds that these arteries, contrary to the usual anatomical description, usually overlie the nerves, that in a series of cases of intracranial tumour the vessels which normally encircle the brain stem often produce a more or less deep grooving of the nervous tissues, that the sixth nerves in many such cases are deeply constricted, and that in a large percentage of cases in which there is found post-mortem grooving of the pons with implication of the nerves, there was recorded during life either subjective diplopia or the actual presence of a convergent squint.

## THE CURRICULUM OF THE MEDICAL STUDENT.

WE publish this week a full report of an important speech made by Sir Henry Morris on the closing day of the winter session of the General Medical Council. An abstract of the speech was published in our columns on Dec. 3rd (p. 1626), but we are glad to place Sir Henry Morris's words before our readers in complete form because the importance of the questions raised is very great, because the solution of these questions is very difficult, and because in our opinion that solution should be no longer delayed. The bald outline of the situation is this. The medical curriculum is overcrowded, so that an unduly small number of candidates for medical qualification are able to obtain registration in the statutory time of five years. Sir Henry Morris, to meet this situation, proposes that the preliminary scientific studies should be pursued by the students at their schools, leaving the five years medical curriculum free for the study of the strictly professional subjects—anatomy, physiology, and medicine in its various branches. One of the strongest points in Sir Henry Morris's arguments is undoubtedly the fact that registration of the medical student is not a compulsory process, so that the General Medical Council has not that complete control over the students' curriculum which some of its published words claim for it. The General Medical Council, on the other hand, holds that, as the supreme authority, under the Privy Council, over the medical education of the student, it cannot willingly sanction any part of medical education being undertaken save under its control. The growing importance in the eyes of headmasters of the scientific training of the schoolboy indicates that much educational and parental feeling will be with Sir Henry Morris in his contention, but those opposed to his view believe, among other things, that the scientific facilities offered by the public schools are not yet as a rule sufficient. These are just the sort of questions that medical men want to see debated, and not only debated but settled, by the General Medical Council.

## FACTORY AND WORKSHOP ACT (1907) IN RELATION TO POOR-LAW ESTABLISHMENTS.

AN arrangement has been made between the Local Government Board and the Home Office with regard to the inspection by inspectors of factories of certain portions of workhouses and other Poor-law establishments. Any laundry or workshop where industrial work is carried on or machinery used, attached to any Poor-law institution, may under the new regulations be inspected by the inspector of factories in charge of the district in which the institution is situated, who will report through the Home Office to the Local Government Board on any point that, in his opinion, requires attention. Where only inmates are employed the factory inspector will report only on the ventilation of the workshop or laundry, the fencing of machinery, the use of dangerous plant or materials, the carrying away of fumes, steam, or dust, and similar matters. Where paid hands, as well as inmates, are employed, the inspector will report on the hours of labour of the paid hands, persons employed only for purposes of supervision or instruction not being regarded as

paid hands. The Local Government Board thinks it very desirable that the factory inspector should, on his visit to a Poor-law institution, be accompanied during his inspection by the master or principal officer in charge, who should afford him every information and assistance, and show him every part of the laundry or workshop in respect of which the visit is made. Where any accident (fatal or other) caused by machinery, explosion, or electricity, or any case of industrial poisoning occurs in any such laundry or workshop, particulars should at once be sent to the factory inspector. Notice should at once be furnished to the factory inspector of the installation of any new machinery in the institution. The new arrangement is obviously most sensible in itself, while it indicates the sound tendency, now existing, towards a more intimate working together of our different Government departments.

## INQUESTS AND DEATHS DURING ANÆSTHESIA.

AT an inquest held on Dec. 12th, 1910, upon a woman who died whilst under an anæsthetic, the coroner, Dr. F. J. Waldo, took the opportunity of explaining his position in holding inquests upon such cases, and invited the opinion of a medical witness on this and other points. As the whole question has been so lately and so thoroughly discussed before the Departmental Committee appointed by the Home Office, whose findings our readers have had the opportunity of perusing, we do not propose to go at length into the matter on this occasion. One or two comments, however, we are minded to pass, in addition to the remarks of the coroner and house surgeon, and especially because the latter offered the opinion, new to us, that the medical press showed insufficient interest in cases of deaths under anæsthetics. We think this is an opinion difficult to arrive at, while it must not be forgotten that the medical press depends to some extent, if its reports are to be quite accurate, for the account of such cases upon the medical men concerned. If the accounts are not forthcoming so freely as the witness in this case appears to desire, then the medical press is necessarily more reticent. Suppression of any such account when it is obviously of scientific or professional interest, is, at any rate so far as THE LANCET is concerned, an unknown event. We do not feel called upon, like the daily press, to narrate the mere occurrence of these deaths. The cases have no value or interest for medical men unless accurate details are supplied. In the lay accounts these are, of course, always wanting. It is of no scientific value to know that on such and such a date a woman died whilst taking ether for an abdominal operation. Such a statement is little more instructive than one to the effect that on another occasion a man took chloroform for an abdominal operation and did not die. But if accurate details as to the time the operation had lasted, exactly what had been done, how the pulse and respiration were acting for some time before the fatal seizure, what loss of blood there had been, how much anæsthetic had been inhaled and how it was administered, and so on, were provided, then the testimony given at coroners' inquests might have some scientific value, and the medical press might find it its duty to report many of the cases. Indeed, it is one of the changes hoped for as a result of the departmental inquiry that in some way the scientific facts associated with every death during anæsthesia may be so collated that a mass of evidence will accrue which will really help future knowledge, instead of, as at present, an inquiry taking place which from the scientific standpoint is valueless. The value of publicity, as making medical men most careful to avoid any conceivable accident, and the danger of publicity, as frightening those who have to undergo operation and who have read of deaths during anæsthesia, were also discussed by the coroner and his witness. Neither of them, however, pointed out what appears to be almost the only merit of the present inquiries—viz., that they safeguard hospitals against the suspicion that would probably exist of them in the minds of the ignorant. Were no such inquiries held the ignorant would often imagine that they were put to the risk of being "experimented upon" in hospitals. Some inquiries are necessary, though the coroner's court is usually an unsuitable tribunal for them.

THE second Hunterian Society's lecture will be delivered at the London Institution, Finsbury-circus, E.C., on Wednesday next, Jan. 11th, at 8 30 P.M., by Mr. D'Arcy Power, on "Loose Cartilages and the Results of their Surgical Treatment." All members of the medical profession are invited to attend.

SEVERAL City Companies and firms, recognising the great value of the public work done by the Royal Society of Medicine, have made grants in aid of the building fund which is being raised by the Fellows to supply the society with a new house.

# THE CHEMISTRY, PHYSIOLOGY, AND ÆSTHETICS OF A CUP OF TEA.[1]

### ULTIMATE *v.* PROXIMATE ANALYSIS OF TEA INFUSION.

CHEMISTRY is not always able to offer a satisfactory explanation of the æsthetic quality of an article. It is doubtful, for example, whether chemical analysis could show any appreciable difference between a good and a bad tobacco, but the æsthetic difference is easy enough to discern. Again, analysis of an elegant château wine reveals comparatively no explanation based on a chemical conception for its refinements; *vin ordinaire*, though very inferior to the palate, shows much the same results on chemical analysis as (say) Château Lafite. The case is the same with tea. Tea apparently is not judged by its chemical qualities, but by its practical qualities, which are determined by the expert tea-taster. In addition to examining the appearance and condition of the leaf he studies very carefully the characteristics of the infusion, its strength or astringency, its flavour, its colour, and its odour. His judgment decides the commercial value of the tea, but whether this judgment means that his valuation is in the economical and physiological interests of the consumer does not appear to have received any extended study.

In most of the chemical literature on the subject it is freely conceded that while a chemical analysis will indicate the strength but not the flavour of the infusion, it is of little use in the valuation of high-priced teas, and this conclusion is drawn in spite of the fact that many thousands of analyses of tea have been made. In the present article we shall attempt to indicate that a very interesting agreement does appear to exist between certain points in the chemical analysis of a tea and the views of the expert tea-taster, provided that the chemical analysis is directed not so much to the percentage amounts of the constituents present as to the relations of these constituents to each other. The question has not been satisfactorily cleared up as to whether these constituents exist in a state of combination, but, if so, it is interesting to ask what are the compounds. What is indicated, therefore, is a proximate rather than an ultimate analysis. To draw an analogy, we have not been content to know merely that there is sodium and that there is chlorine in the sea: we go further, and have found out that these elements are combined in definite quantities to form common salt. Can something of this accuracy be arrived at in respect of tea?

### THE COMMON ACCEPTANCE OF INJURIOUS SUBSTANCES IN TEA.

Undoubtedly the important constituents of tea, as everyone knows, are the alkaloid caffeine (or theine) and tannin. Both, from the physiological point of view, are drugs, the

[1] A contribution from THE LANCET Laboratory.

pharmacology of which is well known, but tannin is generally more unfavourably regarded than caffeine. Tannin, in fact, is commonly looked upon as the source of mischief in excessive tea-drinking. Text-books frequently state that when the tannic acid which tea contains occurs in large quantities, the pepsin of the gastric juice is precipitated, and that this is one of the reasons why tea is not a suitable beverage for persons suffering from gastric disturbances, while among the more prominent symptoms of excessive tea-drinking are gastric disorders, cardiac distress, and a variety of nervous symptoms, such as excitability, sleeplessness, and muscular incoördination. It is a remarkable commentary upon the disfavour with which tannin in tea is looked upon that some of the finest teas (from the tea expert's point of view) upon the market and commanding high prices are just those which contain the largest amount of tannin. A cheap Ceylon tea, for example, was found to yield 5·46 per cent. of tannin in the cup, while a high-priced Ceylon tea showed 7·56 per cent. of tannin. Similarly, a cheap Indian tea gave 5·88 per cent. of tannin to the infusion, and a high-priced Indian tea gave 10 per cent. of tannin, the teas in each case being prepared under analogous conditions. It is again an interesting commentary on the bad name which is given to tannin in tea that a dose of red wine contains more tannin than does a dose of tea. Half a pint of claret, for example, contains on the average 10 grains of tannin, while a cup of tea made with a teaspoonful of leaf (average 60 grains) would contain 6 grains only of tannin. Some teas would, however, yield only half this quantity of tannin in the cup. Tannin in wines, moreover, is in the free active state, in tea it is neutral or fixed. All infusions of tea are alkaline, and they are incapable in that state of acting as a tanning agent. Good teas do not precipitate proteins, nor will they make leather, as is so popularly assumed, the fact being that the tannin in tea is engaged in other directions—an engagement from which it is difficult to divert it. To resume our analogy with which we started, we do not expect common salt solution to have bleaching properties on account of the chlorine contained in it, for we know that the attention of the chlorine is confined completely to the sodium. In the same way the tannin in most teas is engaged, and so rendered inoperative as an astringent or tanning material.

### Evidence of Caffeine and Tannin Existing as a Compound in Tea.

When a warm tea infusion is just acidified with a weak solution of hydrochloric acid the colour of the infusion changes from the well-known reddish-brown to a much lighter colour. At the same time a flocculent precipitate is formed which increases in quantity as the infusion is cooled. The amount of precipitate collected varies with different teas, the China teas yielding the least and the Indian teas the most. The precipitate proves to contain, amongst other things, tannin and caffeine, and, whatever kind of tea is employed, a ratio of 1 to 3 of caffeine to tannin is generally found, which indicates that there is present a real caffeine tannate, having perhaps a formula approximating to the following:—

$C_8H_{10}N_4O_2$ (Caffeine.) $C_{20}H_{20}O_9$ (Quercitannic acid.)

This experiment points distinctly in favour of the conclusion that an infusion of tea is essentially a solution of caffeine tannate in an alkaline medium. When the alkaline salt present in tea is neutralised by the addition of a weak acid, caffeine tannate is gradually thrown out, this substance being only slightly soluble in cold, but readily soluble in hot, water. Now, an infusion of tea as soon as it reaches the acid contents of the stomach would undergo a similar change—that is to say, the human organism is then dealing with a fluid containing part of its caffeine tannate in suspension and part in solution. As will be presently pointed out, this is an important finding, for it indicates that we may not be dealing with either caffeine or tannin in the free state in tea at all. At all events, we have never found in teas classed as of good quality by the tea expert an excess of free tannin or free caffeine. We have, however, found in teas classed as common or indifferent caffeine and tannin dissociated from each other. The foregoing simple experiment suggests, therefore, that the quality of a tea may rest on the question as to whether its constituents are balanced.

### The Estimation of Caffeine Tannate in Tea.

Considerable difficulty was found in hitting off an analytical method which would successfully separate the whole of the caffeine tannate of the tea infusion as such, so that it could be submitted to independent examination; but after some months' experiments a method was obtained which gave very instructive results. It consisted shortly in saturating the infusion with ammonium sulphate, which completely separates the caffeine tannate, which may then be dissolved in absolute alcohol, the alcohol evaporated to dryness, the residue weighed and further examined as to the proportions of caffeine and tannin it contained. (Free tannin itself is soluble in a saturated solution of ammonium sulphate.) In Table A we give the results obtained with various teas when examined by this method.

TABLE A.—*The proportion of Caffeine Tannate in various Tea Infusions and the Composition of the Tannate.*

| Description of tea. | Caffeine tannate or ammonium sulphate precipitate after dissolving in alcohol. | Caffeine found in precipitate. | Tannin found in precipitate. | Approximate ratio of caffeine to tannin in precipitate. |
|---|---|---|---|---|
| | % | % | % | |
| China. | 6·00 | 1·44 | 4·56 | 1 to 3. |
| China. | 6·80 | 1·72 | 5·08 | ,, |
| Indian. | 6·52 | 1·64 | 4·88 | ,, |
| Ceylon. | 4·48 | 1·12 | 3·36 | ,, |
| Indian. | 10·20 | 2·60 | 7·60 | ,, |

It would appear from this table that in tea we are dealing with a definite compound of caffeine and tannin, for although different types of teas were examined, yet the same caffeine-tannin compound was obtained, showing always a constant ratio (1 to 3) of caffeine to tannin. Caffeine tannate is thus probably a definite body, but it does not follow that the whole of the tannin or of the caffeine present in tea infusion is necessarily combined with one or the other, as the case may be. Part certainly is, and in some cases, as will presently be shown, the whole of the caffeine and tannin is united.

### Caffeine Tannate Prepared in the Laboratory.

The next step indicated was to prepare caffeine tannate in the laboratory and to estimate the proportion of the two constituents in the compound. This was done, and the results gave support to the idea that caffeine and tannin form a definite compound containing 1 part by weight of the former, combined with 3 parts by weight of the latter.

Solutions respectively of caffeine and tannin were prepared, each containing 1 per cent. of the pure substance. It is obvious that if 1 part of caffeine combines with 3 parts of tannin to form a compound, 1 volume of the above caffeine solution when added to 3 volumes of the tannin solution should give this compound with neither caffeine nor tannin in excess. A better test, however, would be in the one case to add an excess of caffeine in the mixture and in the other an excess of tannin, and determine in each case what the excess of free substance was. The first experiment consisted in adding 3 cubic centimetres of a 1 per cent. solution of caffeine to 30 cubic centimetres of tannin solution (1 per cent.). A milky fluid resulted which cleared up on heating; it was evaporated to dryness on an inert distributing surface, kieselguhr, and the residue was extracted with ethyl acetate. The ethyl acetate extracted 0·210 gramme of tannin out of 0·30 gramme added, leaving a difference of 0·09 tannin combined with the caffeine. The caffeine added was 0·03 (3 cubic centimetres of a 1 per cent. solution). Thus there was formed a residue containing 1 of caffeine to 3 of tannin. In another experiment it was found that 30 cubic centimetres of tannin solution (1 per cent.) required exactly 19·2 cubic centimetres of N/10 caustic soda to neutralise it, using phenol-phthalein as indicator. When, however, 3 cubic centimetres of a 1 per cent. solution of caffeine was added, the mixture required 14·4 cubic centimetres of N/10 caustic soda for neutralisation. The difference, 4·8 cubic centimetres, represents the amount of tannin which had combined with the 3 cubic centimetres of caffeine solution added (= 0·03). By calculation it was found that 4·8 cubic centimetres of N/10 caustic soda represent 9 cubic centimetres of the tannin (1 per cent.) solution (= 0·09).

and that therefore, again, caffeine had combined with tannin in the proportion of 1 of caffeine to 3 of tannin. This experiment was several times repeated with in each case the same result. Moreover, in some experiments the prepared caffeine tannate was split up by lead oxide and the caffeine separated and weighed. The tannin was estimated by adding dilute sulphuric acid to the lead residue and extracting with ethyl acetate, or determining the tannin after adding an excess of bicarbonate of soda direct by means of a standard iodine solution. Again 1 part of caffeine was found combined with 3 parts of tannin.

Caffeine has a very remarkable affinity for tannin, since in one experiment we found that it will combine with the tannin of leather and reduce it to the soft pulpy condition of untanned hide again, caffeine tannate being found in the solution.

### VARIATIONS IN THE AMOUNTS OF CAFFEINE TANNATE IN TEA.

The next question calling for investigation was, to what extent was the caffeine in tea infusion combined with tannin, or the tannin combined with caffeine? As subsequent experiment proved in many teas (curiously enough all those regarded by tea experts as of good quality), it was found that the *total* caffeine and *total* tannin occurred in the ratio of 1 to 3. In many others there was not this balance, caffeine in some cases being in excess, while in others tannin predominated. The conclusion is irresistible that the physiologically best teas are those in which the total caffeine and total tannin occur in the ratio of 1 to 3—in which, in fact, the caffeine is completely neutralised by the tannin or the tannin by the caffeine, and that therefore they are present as caffeine tannate, and neither in the free state.

Since the above results were obtained we have seen a report, issued from the Imperial Institute, in which the analyses of various teas grown in British Central Africa are given. The following are the results in regard to caffeine and tannin:—

| | Caffeine. | Tannin. |
|---|---|---|
| Tea No. 1 | 3·68 | 10·50 |
| ,, No. 2 | 3·35 | 9·50 |
| ,, No. 3 | 3·08 | 10·30 |
| ,, No. 4 | 3·54 | 10·40 |
| ,, No. 5 | 3·19 | 10·60 |
| ,, No. 6 | 3·22 | 9·80 |

It is remarked that "these results show that the samples of tea are of good quality," and in many instances it will be noted that the ratio of caffeine to tannin is very close to 1 to 3.

### THE PHYSIOLOGICAL IMPORTANCE OF A CHEMICALLY BALANCED TEA AND THE VIEWS OF THE TEA-TASTER.

Tannin may therefore prove after all a blessing in tea, inasmuch as it keeps the assimilation by the human organism of the heart stimulant, caffeine, under control. Similarly, when the constituents are balanced caffeine may be expected to negative entirely the astringent action of the tannin. On the other hand, an excess of either constituent is clearly to be avoided, as each would then be free to exert its own specific action. The points raised by these considerations are clearly of the utmost physiological importance, and we hope to discuss them more fully later. In the meantime, if it comes to be proved that the best teas, physiologically speaking, are those in which the caffeine and tannin are chemically balanced, that they occur completely absorbed by one another as caffeine tannate in which 1 of caffeine is combined with 3 of tannin, it will be interesting to see how far this view agrees with the judgment of the expert taster. Has what he regards as quality in a tea, and therefore a tea entitled to a high price, anything to do with the balance of caffeine and tannin to which attention has been drawn? It is quite clear that caffeine tannate possesses neither the astringent taste of free tannin nor the bitter flavour of free caffeine. Caffeine and tannin serve, not merely as antidotes to each other on the score of taste, but most probably on more important scores also. Tannin is, for example, a well-known antidote to most of the poisonous alkaloids, and caffeine may be reckoned as one of these. It is a remarkable fact that hitherto the results of the chemical analyses of teas have led to nothing in common between the chemist and the taster. Quality in tea so far has been beyond the reach of the analyst to adjudicate upon. He has said what the amounts of caffeine and tannin are, but these mere statements have thrown no light upon the æsthetic and commercial value and quality of the tea submitted to examination. Distinct hope, however, may come from the theory of balance applied to the caffeine and theine in tea which we have put forward. At all events, there are some interesting points of agreement between the expert tea-taster's view and this theory. In Table B will be found a number of analyses of teas which before they were submitted to analysis were each described by the expert taster in terms regarding their æsthetic quality and commercial value. We may say, at the outset, that in by far the majority of instances we were able to show subsequently that his view of the quality of the tea proved to be based upon the question whether or not that tea contained its tannin and caffeine in balanced quantities. Whenever the tea showed a preponderance either of tannin or caffeine over and above that required by the combination of caffeine 1 and tannin 3 his verdict was invariably "a common tea" or "an indifferent tea." When, on the other hand, there was neither caffeine nor tannin present in quantity exceeding what the compound of them contains (caffeine tannate), then the tea was pronounced as of good quality. In other words, the expert, by his palate and other considerations, says, in effect, the caffeine and tannin in such and such a tea are not balanced, therefore it is not a fine tea, or the caffeine and tannin are present in a combined state and therefore the tea is bland, smooth, and a good one. In the case of an inferior tea he probably tastes either free caffeine, which is bitter, or free tannin, which is astringent, and promptly calls the tea unsuitable. In the case of the fine tea he tastes neither, but a combination of them, which is neither astringent nor bitter. When contrasting chemical results with the skill of the taster a complete concordance can hardly be expected, but Table B shows broadly that the palate of the taster is largely influenced by the chemistry of the tea submitted to his judgment. To go back to the old analogy, common salt has a neutral smooth saline taste, but if either of its constituents is in excess the taste would be repulsive—viz., that of caustic alkali on the one hand, or of a corrosive acid on the other.

On consulting Table B it will be found that, generally speaking, the common (and cheap) teas contain an excess of caffeine over tannin present, but the good teas (high-priced) invariably contain an excess neither of caffeine nor of tannin, these being present in complete combination in the form of caffeine tannate. It is possible that by a careful system of blending these excesses could be to some extent avoided, but we must defer for a later stage the consideration of blending. It is interesting to observe also that proteins increase with the quality of the teas, and as proteins form an insoluble compound with tannin the evidence is thus strengthened in favour of no free active tannin being present in good tea-infusions. It is well-known, also, that teas have to be adapted to the various characteristics of the waters of different neighbourhoods, and it is conceivable that the balance of caffeine and tannin may be disturbed by, for example, chalk, which would tend to combine with tannin and liberate free caffeine. Here, also, the art of blending possibly aims at securing the equilibrium of tannin and caffeine already pointed out, taking into consideration the effect of a hard or soft or peaty water on the soluble constituents of the tea. In this connexion it is interesting to record that the tea-taster has samples of the water of different localities sent to him so that he can decide which tea gives the best result with it. There is only one instance in the Table (B) in which tannin is in serious excess, and that, curiously enough, is green tea, and in addition there is present 1·28 per cent. of caffeine not combined with tannin. *Prima facie* it is doubtful whether tannin is ever an injurious constituent of ordinary teas; it is much more likely that caffeine is the mischief-maker, especially when a considerable portion of that alkaloid does not occur combined with tannin, as is invariably the case with common cheap teas. It is questionable, too, whether the powerful are more injurious than the delicate teas so long as the caffeine and tannin are in balanced quantities—are, so to speak, in physiological equilibrium. The danger of the rich tea (although of good quality) is taking an excess of it, which can, of course, be avoided by using it sparingly, and thereby

The above percentage results are based on the use of 5 grammes of tea in 400 cubic centimetres of boiling water, the infusion being poured off after five minutes.

effecting an important domestic economy. So many people seem to disregard the fact that the powerful teas should be employed in quantities consistent with their rich quality. In the above analyses many of the good teas present twice the physiological value of the common teas, although their price may be only 50 per cent. more, if as much. It is illogical, therefore, to adopt the teaspoonful as the standard of measurement for all descriptions of teas; the dose might with advantage be reduced to a decidedly smaller quantity in the case of balanced teas which give a rich infusion. It is commonly asserted that when tea is infused for a long time there is much more tannin dissolved in proportion to the caffeine. That may be true for teas of common quality or cheap teas, but in one experiment we made it does not appear to hold good for a tea of good quality. A good Indian tea, for example, gave on 5 and 15 minutes' infusing respectively the following results:—

| | 5 minutes (per cent.). | 15 minutes (per cent.). |
|---|---|---|
| Caffeine tannate ... ... ... ... ... | 10·40 | 10·68 |
| Tannin combined with caffeine ... ... | 7·80 | 8·73 |
| Caffeine combined with tannin ... ... | 2·60 | 2·68 |

It will be observed that more tannin was extracted but more caffeine was extracted also. In reality, with a good tea more caffeine tannate and not tannin is extracted. The ratio 1 in 3 of caffeine to tannin is, in fact, preserved in the 15 minutes' infusion. The suggestion of this is that it matters little whether a good tea be infused for a longer time, but, of course, a stronger liquor is obtained, which should be diluted or less tea employed. This consideration hinges again on the question of blends, and at the present time we are engaged on further analytical work on the question with the view of ascertaining whether the blender unconsciously aims, after all, at producing the equilibrium of tannin and alkaloid to which we have referred. At the moment it is premature to regard the case which we have put to be absolutely proven, but the investigation so far has certainly brought to light an interesting set of facts based on chemical analysis which show a remarkable agreement with the views of the expert tea-taster. We should expect to find from these results, for example, that when he regarded a tea as one of good quality, the caffeine and tannin would appear practically entirely in the form of a combination, caffeine tannate. In the case of a tea which he puts aside as common or indifferent, we should expect to find that the caffeine present was not in affinity with the tannin. Possibly we are dealing with young tender leaves when the caffeine and tannin are found in equilibrium, and old or coarse leaves when that is not the case. This conclusion is interesting in view of the fact that tannin happens to be an antidote to alkaloids in general, and commonly forms with them substances which are at any rate insoluble in the stomach, though they would be absorbed in the bowel. Is it not possible that the absorption of caffeine is less rapid when it is present with an equivalent of tannin, and that, therefore, the common teas which contain caffeine not in combination with tannin easily lead to theinism, caffeine poisoning? After all, caffeine is a powerful drug, increasing the strength and rapidity of the heart's action and the blood pressure, and it is possible that its potency in this direction is favourably modified when it is exhibited with an exact equivalent of tannin, as is the case with teas passed by the expert as of good quality, "fine," and so forth. Both constituents can behave badly physiologically when in the free state, but when in a mutual combination their vices are lost in the marriage and their virtues come uppermost. That seems to describe the case of a good tea. Tannin cannot "tan" in the presence of an equivalent of caffeine, and the poisonous qualities of caffeine are very probably diminished in intensity when it exists entirely as tannate.

We reserve for future publication further researches on the subject which are proceeding.

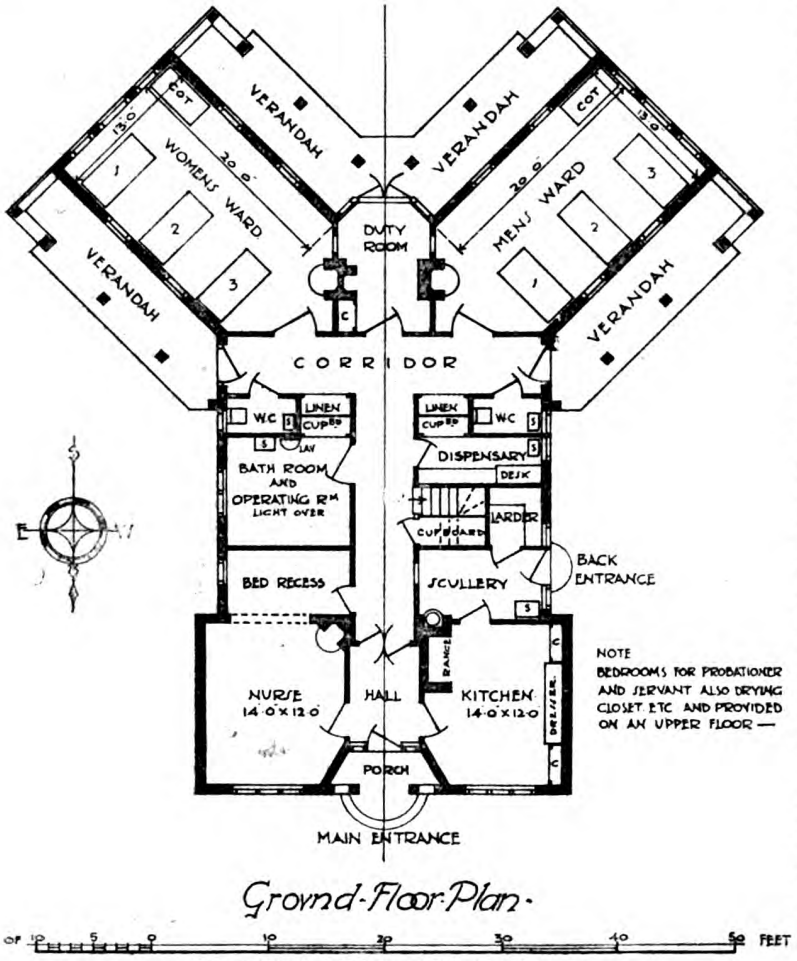
CHELSEA HOSPITAL FOR WOMEN.—The annual entertainment organised by the ladies' committee for the patients and nurses was given at the hospital on Thursday, Dec. 29th, when the visitors were received by Viscountess Esher, the vice-president of the ladies' committee. After tea a clever conjuring entertainment by Mr. Lambert was much enjoyed, and later there was a distribution from a Christmas tree laden with useful presents for the inmates, which were the gift of Dr. W. H. Fenton, senior surgeon, and Mrs. Fenton. On Saturday last the Christmas festivities were brought to a close by a concert arranged by Mr. Michael Fenton with the help of the following: Miss Millie Hall, Miss Barbara Zitzer, Mr. Alec Aris, Mr. Ivan Ayscough, and Mrs. Frank Snow. The work in the wards of the hospital during the past year shows a marked increase, the number of admissions being 870, as compared with 803 for 1909. Provision for those of small means, under conditions which will allow of some privacy of treatment, are features marking this hospital out for charitable support. The treatment of the patients is supplemented by reception at a convalescent home at St. Leonards-on-Sea. The regular income is much in need of increase, and donations and legacies are earnestly solicited towards rebuilding the out-patient department and the nurses' home, the present accommodation being entirely inadequate. Contributions will be gratefully acknowledged by the treasurer, Mr. Henry E. Wright, or the secretary, Mr. Herbert H. Jennings, at the hospital, Fulham-road, S.W.

# A WELL-PLANNED COTTAGE HOSPITAL.

THE small cottage hospital at Wells, Norfolk, which has been erected by the Holkham tenantry as a memorial to the late Earl of Leicester, was recently opened by the present Earl. Situated near the seaport town of Wells, this hospital will supply an isolated district of north Norfolk, over 30 miles from the county institution at Norwich, the population of Wells and the neighbouring agricultural villages being about 7000. Inquiries are often made from us as to the best way of meeting the needs for a cottage hospital in just such a community. Mr. Leslie T. Moore, A.R.I.B.A., of Raymond Buildings, Grays Inn, W.C., the architect, sends us a description of the building, of which the illustration shows the general scheme.

The building provides for six adult patients and two cots, and has been erected for the moderate sum of £1000, including the sinking of a well and fencing the site, which was generously given by Lord Leicester. The plan of the building is somewhat original in its outline, being in the shape of the letter "Y," the wards forming the short arms, while the administrative portion of the building forms the stem with main entrance from the north. All the advantages of aspect and cross ventilation are thus gained for the wards, which are 12 feet high and give a cubic capacity of 1000 feet per patient. They are amply ventilated by the large windows in the end gables, in addition to those at the side of each bed. Between the wards a small duty-room is arranged for supervision, from which there is at the same time command of the corridor. Verandahs for convalescent patients are so planned that from whichever direction the wind blows shelter can be obtained. The ground floor throughout is laid with non-absorbent jointless flooring with core skirtings. Internally all mouldings and projections likely to harbour dust and germs have been dispensed with. The wards and corridors have an impervious dado painted white, with washable enamel paint, the whole of the joinery being similarly finished. Over a portion of the building an upper floor provides bedrooms for a probationer and servant, also a drying closet and store-rooms for patients' clothes, &c. Special attention has been given to the sanitary fittings, the best white porcelain enamel fireclay being used throughout. The cubic capacity of the wards as built at Wells is 3600 cubic feet. All the windows to the wards are double hung sashes and are fitted with Dr. Hinkes Bird's patent deep bead at bottom admitting the air between the meeting rails in a vertical direction. The windows to the administrative portion of the building are of the cottage casement type, giving a homely appearance. The transverse corridor with external doors to verandahs at either end forms a "cut off" between the wards and offices. The fires are of the barless slow-combustion type with green glazed fireclay mantles and hearths. The bathroom was especially designed rather larger than necessary and with a top light so that emergency operations could be undertaken. The walling generally is of brick built in cement, the outer walls being 9 inches thick with 3-inch cavity, and Silverlock's method of bond being adopted. The external face of the walling is rough-casted in cement.

In response to our inquiry as to the possibility of effecting economy in the cost of such buildings and the additional expense of enlargement Mr. Moore writes as follows: "Concrete blocks could be substituted with a slight saving in cost if gravel of a suitable nature could be obtained on the site of building, but the advantages of a hollow wall, which are all-important, would be sacrificed. Further economy might be effected if Bridgwater tiles or other patent roofing were adopted in place of the hand-made tiles that were used in this instance. But such roofing would be detrimental to the general appearance of the building. The plan especially adapts itself for future extension of the wards, which could be lengthened and another bed added to each ward for an extra cost of about £125, making four male and four female adult beds and two cots. But any further extension would require larger administrative offices, and would consequently necessitate a greater outlay in proportion."



Cottage Hospital, Holkham, Wells, Norfolk.

A BRAVE MEDICAL MAN.—At Penzance, on Dec. 19th last, Colonel Cornish, on behalf of the Royal National Lifeboat Institution, presented Mr. Richard Coger Lawry, L.R.C.P. Lond., M.R.C.S. Eng., with the certificate of the Royal Humane Society. Mr. Lawry, with two other gentlemen, rescued a bather from drowning off Laregaw, Cornwall, on August 6th, 1910.

# Public Health.

## REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*On the Sanitary Circumstances and Administration of the County Borough of Middlesbrough, with Special Reference to the Persistently High General Death-rate and Infantile Mortality and their Causes*, by Dr. W. W. E. FLETCHER.[1]—In this report Dr. Fletcher gives the results of an elaborate study of the statistics of mortality in Middlesbrough for recent years and of the conditions associated with some unusually high figures which appear characteristic of that town. Middlesbrough is almost entirely inhabited by a working-class population, and has grown rapidly with the development of the industries which resulted from the utilisation of the ironstone in the Cleveland Hills. There are now some 107,000 inhabitants—a population nearly double that of 1881, and more than four times that of 1861. The general death-rate is persistently higher than that of the "great towns" dealt with by the Registrar-General; the mean annual crude death-rate for the 12 years 1896–1907 was 16·5 for the latter and 20·1 for Middlesbrough. The discrepancy becomes greater when corrections are made for the age and sex distribution of the populations. From a detailed analysis of the causes of death in 1907 Dr. Fletcher ascertained that an excessive mortality existed from the "zymotic" group of diseases (notably from diarrhœa and enteric fever) and from pneumonia, while there was also a considerable excess of deaths grouped as due to "diseases of the nervous system" and "atrophy and debility." In the five years 1904–1908, the mean annual death-rate from diarrhœa per 1000 living under one year, was 30·8 for Middlesbrough, as against 8·9 for England and Wales. In reviewing the causes of this excess of diarrhœa the report lays stress upon the frequent inability of mothers to suckle their infants owing to insufficiency of food and upon the use of tinned separated milk in baby-feeding. From enteric fever the annual death-rate per 1000 inhabitants during the same five years was 0·17 in Middlesbrough, as against 0·10 in England and Wales. The difference in mortality ascribed to pneumonia is still more conspicuous; the Middlesbrough mean annual rate of 3·41 per 1000 is more than double the corresponding rate for the country generally. "Pneumonia," in the statistical sense of the report, includes both broncho-pneumonia of children, which prevails largely during the winter, and lobar pneumonia, which was found to predominate in the spring. In 1888, when Middlesbrough suffered from a special prevalence of pneumonia, investigated for the Local Government Board by the late Dr. E. Ballard, the incidence of the disease was essentially upon middle-aged and old persons. No very disproportionate incidence upon any one age-group has, however, characterised the fatal "pneumonia" of Middlesbrough in recent years. Compared with England and Wales, the Middlesbrough figures show a higher actual death-rate among females, but a much lower rate relatively to the males. The conditions of work in iron-smelting lead to such sudden changes in body temperature and give such facilities for taking chills that the excess of pneumonia might have been expected to be conspicuous among the ironworkers. No such excess could be demonstrated on statistical evidence. Dr. Fletcher, however, expresses doubts as to the sufficiency of the occupational returns available for the purpose. The clinical and bacteriological characters of the pneumonia at present met with in Middlesbrough do not appear to be exceptional. Dr. Fletcher considers that the fact that the excess runs through all age-groups indicates that the whole population is more or less uniformly affected by some influence which appears to predispose individuals of each age-group, but more especially the males, to attack. At present the nature of this influence cannot be definitely stated. When, however, the conditions of life of the population are considered in relation not only to pneumonia but also to enteric fever, diarrhœa, and other diseases in which mortality is excessive, it is difficult to resist the impression that common factors exist in the insanitary surroundings of dwellings, the bad ventilation of houses, overcrowding, want of sufficient and wholesome food and of proper clothing, exposure to inclement weather, and other deleterious conditions, which, as Dr. Fletcher shows, prevail to an unusual extent in the town. The report contains a variety of statistics as to age and sex distribution of the diseases referred to, which will be found useful for reference. Some of the deficiencies of sanitary administration to which Dr. Fletcher refers appear to have been rectified by the town council before the publication of the report, but there is evidently need for an active policy being undertaken by the municipal authorities in regard to housing, health visiting, nuisance abatement, improved water filtration, and other matters, in order to reduce so far as in their power the unenviable pre-eminence of Middlesbrough in respect of sickness and mortality.

*On Occurrences of Enteric Fever in the Folkestone Urban District*, by Dr. R. W. JOHNSTONE.[2]—Dr. Johnstone in this report presents a remarkable series of facts, implicating a typhoid carrier as the cause of no fewer than five outbreaks of enteric fever, associated with milk, between the years 1893 and 1909. The man in question, a milker, N., was ascertained to be a carrier in 1909, when the typhoid bacillus was isolated from the fæces on five separate occasions on which samples were taken. He was about 60 years of age and enjoyed excellent health. To his knowledge he had never suffered from enteric fever, although he had been attacked by a severe illness of an uncertain kind about 30 years before. He had become a regular milker in 1893, when he came to a farm in the Elham rural district, close to Folkestone, and from that time until August, 1909, he had been employed on five farms near to the town. At three of these farms enteric fever broke out during N.'s stay, and cases of enteric fever occurred in the neighbourhood of all five of them whilst he was there. On the milk round of each of the five farms there was undue prevalence of enteric fever at intervals during the time N. worked there, and no such prevalence was observed either before his advent or after his departure. During the period 1896–1909 64 per cent. of the cases of enteric fever infected in Folkestone were persons who had taken milk from a farm in which N. was working. The outbreaks had attracted considerable attention, and their origin and relation to the milk-supplies had been fully investigated as they occurred. The suspicion that the milker N. was in some way or other concerned with the infectiousness of the milk at the places where he worked had been entertained by Mr. Pearson, the Folkestone inspector of nuisances, as long ago as 1900, before bacteriology had demonstrated the existence of the chronic carrier, and between that year and 1909 this inspector had paid special attention to N.'s movements and had traced numerous cases of enteric fever to milk from farms at which N. worked. On reviewing the facts at the present time it was possible to refer to this carrier the infection of as many as 230 persons during the period 1893–1909 distributed year by year as follows:—

| | | | |
|---|---|---|---|
| 1893 | 1 | 1902 | 16 |
| 1894 | 3 | 1903 | 7 |
| 1895 | 4 | 1904 | 5 |
| 1896 | 17 | 1905 | — |
| 1897 | 21 | 1906 | 2 |
| 1898 | 14 | 1907 | 3 |
| 1899 | 68 | 1908 | 5 |
| 1900 | 38 | 1909 | 14 |
| 1901 | 12 | | |

Dr. Johnstone points out that the N. milk was supplied in two districts for three months during 1901 without any known increase of enteric fever in those districts, and that no cases could be attributed to N. milk during the year 1905. Neither of these facts is, however, sufficient to disprove a carrier hypothesis, as N. may have been only intermittently in an infectious condition, while even if his condition was one of continued infective ability it was not inevitable that infection should always reach the milk-supply. The principal results of Dr. Johnstone's inquiry are referred to in the special report made by Dr. J. C. G. Ledingham to the Local Government Board on enteric fever carriers, which was reviewed in THE LANCET of Dec. 3rd last, p. 1631. Dr. Johnstone's report should, however, itself be carefully studied by all who desire

[1] Reports to the Local Government Board on Public Health Subjects (New Series, No. 42). London: Wyman and Son, Fetter-lane; Edinburgh: Oliver and Boyd; Dublin: E. Ponsonby. Price 8*d*.

to realise the weight of the circumstantial evidence which supports this remarkable example of continuity of carrier infectivity.

### ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

*City of Sheffield.*—The population of this city as estimated by the Registrar-General amounted in 1909 to 470,958, and it may be noted that the extension of the city limits in 1901 added some 25,000 to 30,000 to the population. In 1890 the population was only 321,079. The birth-rate for 1909 amounted to 28·2 per 1000, which was considerably below that of any previous year. The marriage-rate was also the lowest yet recorded—i.e., only 14·6 per 1000 persons married. Under the above circumstances there is some satisfaction in being able to record that the death-rate, 15·07 per 1000 for the year, beat all previous records, as did the infantile mortality figure, which was only 119 per 1000 births, the lowest figure previously recorded having been 141 per 1000 births. Dr. Harold Scurfield furnishes some interesting data relative to industrial phthisis, but it would add to the interest of the figures if we could be told how much of this phthisis is tuberculous. Amongst grinders aged 18 years and over the average death-rate from phthisis for the nine years 1901–09 was 15·1, that of cutlers 5·8, of file cutters 5·2, silver workers 5·5, tailors 1·5, printers 3·7, and joiners 1·7 per 1000 in each instance, while the phthisis death-rate amongst all males aged 20 and over was 2·7 per 1000. In connexion with the question of pulmonary tuberculosis and "phthisis" an instructive table is furnished showing the death-rate from these combined diseases in Sheffield since 1839, together with the percentage of total deaths which took place in the workhouse. It would be of interest if curves could be made showing the relation between the phthisis death-rate and the percentage of deaths occurring in the workhouse. Dr. Scurfield reprints in his annual report the paper which he read at the Tuberculosis Congress in Edinburgh,[1] wherein he sets forth the provision made in Sheffield for dealing with cases of tuberculosis in the educational, therapeutic, isolation, and after-care phases. There is no municipal sanatorium at Sheffield, but £1000 annually are available for sending suitable cases to other sanatoriums. It would not, the medical officer of health declares, be possible in the absence of an invalidity insurance scheme to fill a 40-bed sanatorium with suitable cases from Sheffield—a somewhat significant statement made in relation to a population of nearly half a million. He thinks, also, that as things have developed in Sheffield a dispensary would be of no advantage, since all that could be done by such an institution is already provided for in the office of the medical officer of health and the out-patient department, as both of the city hospitals coöperate in the scheme. One of the weak points in the present scheme in Sheffield is, as is obvious elsewhere in this country, the fact that the bread-winner usually remains at work until his disease has passed the curable stage, and the only remedy for this, as was demonstrated in the Local Government Board report upon sanatoriums, is the introduction of some scheme such as the compulsory insurance system in Germany. There is in Sheffield a by-law against spitting in public carriages, halls, or waiting-rooms, but the medical officer of health thinks that spitting upon footpaths ought to be prohibited, and that chronic bronchitics should use pocket spittoons. In Dr. Scurfield's opinion the most striking point brought out at the Edinburgh Congress was the extraordinary percentage of human beings who become infected with tuberculosis at some period of their lives and whose disease is only recognised at the post-mortem examination. But, of course, a great deal of this has been known and appreciated amongst the Germans for many years, as is shown by the saying that everyone has at the end a focus of tuberculosis. With regard to bovine tuberculosis, Dr. Scurfield regards the present method of searching out cows with tuberculous udders as a clumsy makeshift. It appears, nevertheless, from the report of the veterinary surgeon that the number of tuberculous udders discovered during 1909 was greater than in any previous year—a fact which speaks well for the increasing efficiency of the inspection. The Sheffield report upon the Home Office inquiry as to the effects of the industrial employment of women on child-bearing and infantile mortality is contained in the annual volume before us, where some of the conclusions are thus summarised: "The group of mothers not industrially employed is better than any of the groups of mothers industrially employed as regards infant mortality, as regards the number of births, and as regards the liability to premature live births, whether judged by the births forming the subject of the inquiry or by the records of the past, but it has to be remembered that the number of industrially employed mothers is very small."

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7973 births and 4611 deaths were registered during the week ending Dec. 24th, 1910. The annual rate of mortality in these towns, which had decreased from 18·1 to 15·2 per 1000 in the three preceding weeks, further declined to 14·2 in the week under notice. During the first 12 weeks of the quarter the death-rate in these towns averaged 14·7 per 1000. In London during the same period the death-rate, calculated on a probable over-estimate of its population, was equal to 15·3 per 1000. The annual death-rates in the 77 towns in the week under notice ranged from 6·8 in Stockton-on-Tees, 7·9 in Northampton, 8·6 in Smethwick, and 9·1 in Willesden and in Derby, to 21·4 in Preston, 21·6 in Stoke-on-Trent, 25·4 in Dewsbury, and 25·9 in Rotherham. The 4611 deaths from all causes in the 77 towns during the week showed a decrease of 335 from the number in the preceding week, and included 442 which were referred to the principal epidemic diseases, against 332 and 397 in the two preceding weeks; of these 442 deaths, 208 resulted from measles, 64 from diarrhœa, 61 from whooping-cough, 56 from diphtheria, 28 from enteric fever, and 25 from scarlet fever, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases, which had been 1·0 and 1·2 per 1000 in the two preceding weeks, further rose to 1·4 in the week under notice. No death from any of these epidemic diseases was registered in Leyton, Halifax, Walsall, York, Aston Manor, Devonport, or in seven other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·7 in Tottenham, 2·9 in Middlesbrough, 3·5 in Grimsby, 4·5 in West Hartlepool, and 7·1 in Rotherham. The fatal cases of measles in the 77 towns, which had been 143 and 169 in two preceding weeks, rose again to 208 in the week under notice; the highest annual rates from this disease in the week were 2·0 in Tottenham, 2·5 in Plymouth and in West Hartlepool, 3·5 in Grimsby, and 3·9 in Rotherham. The 64 deaths attributed to diarrhœa showed a slight increase compared with the number in the previous week. The 61 deaths from whooping-cough were equal to the number recorded in the previous week, and caused the highest rate in Middlesbrough. The 56 deaths referred to diphtheria was the highest number recorded in any week of the year, and included 16 in London, 5 in Leeds, 4 in King's Norton, and 3 each in Portsmouth and Birmingham. The deaths from enteric fever, which had been 21 and 26 in the two previous weeks, rose to 28 in the week under notice; 7 deaths occurred in London and 2 each in Wigan, Burnley, Preston, and Bradford. The 25 deaths from scarlet fever showed a decline from the numbers in the two previous weeks; 4 deaths were registered in Liverpool, 4 in Salford, 3 in Stoke-on-Trent, 3 in Birmingham, 2 in Manchester, and 2 in Huddersfield. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had declined in the six preceding weeks from 1882 to 1680, had further fallen to 1627 on Saturday, Dec. 24th; 167 new cases of this disease were admitted to these hospitals during the week, against 170, 169, and 156 in the three preceding weeks. The 1309 deaths from all causes in London in the week under notice included 261, which were referred to pneumonia and other diseases of the respiratory system, against numbers which had decreased from 669 to 355 in the three preceding weeks; these 261 deaths were 150 fewer than the corrected average number in the corresponding week of the five years 1905–09. The causes of 29, or 0·6 per cent.,

of the deaths registered during the week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in the week under notice in Leeds, Bristol, West Ham, Newcastle-on-Tyne, Hull, Leicester, Stoke-on-Trent, Salford, and in 50 other smaller towns; the 29 uncertified causes of death in the 77 towns included 5 in Liverpool, 3 in Birmingham, 3 in Sheffield, 2 in St. Helens, and 2 in South Shields.

In 77 of the largest English towns 6915 births and 4591 deaths were registered during the week ending Dec. 31st, 1910. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 18·1 to 14·2 per 1000, further fell to 14·1 in the week under notice. During the 13 weeks of the past quarter the death-rates in these towns averaged 14·7 per 1000, against 14·8 and 14·3 in the corresponding quarters of 1908 and 1909. In London the death-rate last quarter was equal to 15·3 per 1000, against 13·7 and 13·5 in the two preceding corresponding quarters. The annual death-rates in the 77 towns during the week under notice ranged from 5·0 in Smethwick, 5·1 in West Hartlepool, 7·4 in King's Norton, and 7·8 in Wallasey, to 20·4 in Dewsbury, 22·0 in Rotherham, 23·1 in Huddersfield, and 24·0 in Tynemouth. The 4591 deaths from all causes in the 77 towns in the week under notice showed a further decline of 20 from the decreasing numbers in the four preceding weeks, and included 391 which were referred to the principal epidemic diseases, against 332, 397, and 442 in the three preceding weeks; of these 391 deaths, 185 resulted from measles, 55 from diphtheria, 54 from whooping-cough, 51 from diarrhœa, 25 from enteric fever, and 21 from scarlet fever, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the 77 towns was equal to 1·2 per 1000, against 1·2 and 1·4 in the two preceding weeks. No death from any of these epidemic diseases was registered in the week under notice in East Ham, Birkenhead, Wolverhampton, Walsall, York, Aston Manor, and King's Norton; the annual rates therefrom ranged upwards, however, to 2·9 in Great Yarmouth and West Bromwich, 3·6 in Brighton, and 6·3 in Rotherham. The fatal cases of measles in the 77 towns, which had been 169 and 208 in the two previous weeks, declined again to 185 in the week under notice; the highest annual rates from this disease last week were 1·8 in Bury and in Oldham, 2·1 in Grimsby, 2·4 in Brighton, and 4·7 in Rotherham. The 55 deaths referred to diphtheria were within one of the number in the previous week, and included 22 in London and its suburban districts, and 3 both in Liverpool and in Manchester. The 54 deaths from whooping-cough showed a decline of 7 from the number returned in each of the two preceding weeks; the annual rate from this disease was equal to 1·3 in Newcastle-on-Tyne and 1·6 in Rotherham. The 51 deaths attributed to diarrhœa were fewer by 13 than the number in the previous week. The deaths referred to enteric fever, which had been 21, 26, and 28 in the three preceding weeks, declined last week to 25, of which 5 occurred in London, 4 in Manchester and Salford, 3 in Preston, and 2 each in Portsmouth, Liverpool, and Hull. The fatal cases of scarlet fever, which had been 30, 28, and 25 in the three preceding weeks, further declined last week to 21, and included 5 in Manchester and Salford, 3 in London, 2 in Liverpool, and 2 in Norwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily declined in the seven preceding weeks from 1882 to 1627, had further fallen to 1594 on Saturday, Dec. 31st; 138 new cases of this disease were admitted to these hospitals during the week, against 157 and 167 in the two previous weeks. The 1356 deaths from all causes in London in the week under notice included 263 which were referred to pneumonia and other diseases of the respiratory system, against 355 and 261 in the two preceding weeks; these 263 deaths were fewer by 119 than the corrected average number in the corresponding week of the five years 1905–09. The causes of 41, or 0·9 per cent., of the deaths registered during the week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Nottingham, Leicester, and in 50 smaller towns; the 41 uncertified causes of death in the 77 towns in the week under notice included 10 in Liverpool, 4 in Birmingham, and 3 in Sheffield.

## HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 823 births and 486 deaths were registered during the week ending Dec. 24th, 1910. The annual rate of mortality in these towns, which had decreased in the three preceding weeks from 17·5 to 16·5 per 1000, further declined to 13·4 in the week under notice. During the first 12 weeks of the quarter the death-rate in these eight towns averaged 14·8 per 1000, and was slightly above the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns in the week under notice ranged from 8·9 and 10·7 in Paisley and Aberdeen to 19·6 in Perth and 20·8 in Dundee. The 486 deaths from all causes in the eight towns during the week showed a decline of 112 from the number in the previous week, and included 40 which were referred to the principal epidemic diseases, against 47, 40, and 50 in the three preceding weeks; of these 40 deaths, 12 resulted from whooping-cough, 11 from diarrhœa, 10 from diphtheria, 6 from scarlet fever, and 1 from "fever," but not one from small-pox or from measles. The mean annual rate of mortality from these epidemic diseases in the eight towns in the week under notice was equal to 1·1 per 1000, or 0·3 below the rate from the same diseases in the 77 English towns. The 12 deaths referred to whooping-cough in the eight towns showed but slight variation from the numbers in recent weeks, and included 3 in Glasgow, 3 in Dundee, and 2 both in Aberdeen and in Greenock. The fatal cases of diarrhœa, which had been 9 in each of the two preceding weeks, were 11 in the week under notice, of which 5 were returned in Glasgow and 5 in Dundee. The deaths attributed to diphtheria, which had been 11, 13, and 18 in the three preceding weeks, declined to 10 during the week, of which 6 were recorded in Glasgow and 2 in Dundee. Of the 6 deaths from scarlet fever, 2 occurred in Dundee, and 1 each in Glasgow, Edinburgh, Paisley, and Perth. The fatal case of "fever" was registered in Dundee. The deaths referred to diseases of the respiratory system in the eight towns, which had decreased from 157 to 122 in the three preceding weeks, further declined to 117 in the week under notice, and were 56 below the number in the corresponding week of last year. The causes of 15, or 3·1 per cent., of the deaths in the eight towns in the week under notice were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death did not exceed 0·6 per cent.

In Glasgow 429 births and 245 deaths were registered in the week ending Dec. 31st, 1910. The deaths exceeded the number in the previous week by 22, and were equal to an annual rate of 14·5 per 1000, against 17·2 and 13·2 in the two preceding weeks. The 245 deaths included 18 which were referred to the principal epidemic diseases, of which 9 resulted from diarrhœa, 5 from diphtheria, 2 from scarlet fever, and 1 each from whooping-cough and enteric fever, but not 1 from measles or small-pox; these 18 deaths were equal to an annual rate of 1·1 per 1000. The 9 deaths attributed to diarrhœa exceeded the number in the previous week by 4; the 5 fatal cases of diphtheria showed, however, a decline of 1. The deaths referred to diseases of the respiratory system, which had been 69 and 52 in the two previous weeks, declined to 47 in the week under notice. Ten deaths were the result of violence, and 80 were recorded in public institutions. The causes of 6, or 2·4 per cent., of the deaths were not certified. In Edinburgh 134 births and 102 deaths were registered in the week under notice. The deaths exceeded by 21 the number returned in the preceding week, and were equal to an annual rate of 14·8 per 1000, against 15·8 and 11·7 in the two preceding weeks. The 102 deaths included 7 which were referred to the principal epidemic diseases, of which 5 resulted from diphtheria and 1 each from scarlet fever and diarrhœa, but not one from measles, whooping-cough, enteric fever, or small-pox; these seven deaths were equal to an annual rate of 1·0 per 1000. The fatal cases of diphtheria in the city, which had been 3, 8, and 1 in the three preceding weeks, rose again to 5 in the week under notice. The deaths referred to diseases of the respiratory system in Edinburgh, which had been 28, 22, and 19 in the three preceding weeks, rose again to 20 in the week under notice. Four deaths were the result of violence, and 34 were recorded in public institutions. The causes of 2, or

2·0 per cent., of the deaths registered during the week were not certified.

### HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 477 births and 423 deaths were registered during the week ending Dec. 24th, 1910. The mean annual rate of mortality in these towns, which had been 19·6 per 1000 in each of the two preceding weeks, declined to 19·1 in the week under notice. During the first twelve weeks of the quarter the annual death-rate in these Irish towns averaged 17·6 per 1000; the mean rate during the same period did not exceed 14·7 in the 77 largest English towns and 14·8 in the eight Scotch towns. The annual death-rate during the week was equal to 21·6 in Dublin, 17·6 in Belfast, 17·1 in Cork, 18·0 in Londonderry, 10·9 in Limerick, and 13·6 in Waterford; the mean annual death-rate in the 16 smallest of these Irish towns in the week under notice was equal to 21·3 per 1000. The 423 deaths from all causes in the 22 town districts in the week showed a decline of 9 from the number in the previous week, and included 25 which were referred to the principal epidemic diseases, against 33 and 23 in the two previous weeks; these 25 deaths were equal to an annual rate of 1·1 per 1000; in the 77 English towns the mean rate from the same diseases was 1·4 per 1000 and 1·1 in the eight Scotch towns. The 25 deaths from these epidemic diseases in the Irish towns in the week under notice included 9 from measles, 6 from whooping-cough, 5 from diarrhœa, 3 from diphtheria, 1 from scarlet fever, and 1 from enteric fever, but not one from small-pox. The fatal cases of measles, which had been 5 and 10 in the two preceding weeks, were 9 in the week under notice, and included 6 in Lurgan. The 6 deaths from whooping-cough showed an increase of 4 on the number in the previous week; 5 deaths were recorded in Dublin and 1 in Belfast. Of the 5 fatal cases of diarrhœa 2 occurred in Dublin. Of the 3 deaths from diphtheria 2 were registered in Dublin and 1 in Portadown. The fatal case of enteric fever was recorded in Dublin, and that of scarlet fever in Belfast. The deaths in the 22 towns during the week included 146 which were referred to pneumonia and other diseases of the respiratory system, against numbers increasing from 80 to 130 in the five preceding weeks. The causes of 20, or 4·7 per cent., of the deaths registered in the Irish towns in the week under notice were not certified; in the 77 English towns the proportion of uncertified deaths did not exceed 0·6 per cent., and in the eight Scotch towns it was equal to 3·1 per cent.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 584 births and 371 deaths were registered during the week ending Dec. 31st, 1910. The mean annual rate of mortality in these towns, which had been equal to 19·6 and 19·1 per 1000 in the two preceding weeks, declined to 16·8 in the week under notice. During the 13 weeks of the past quarter the annual death-rate in these Irish towns averaged 17·6 per 1000; the mean rate during the same period did not exceed 14·7 in the 77 largest English towns, and 14·8 in the eight principal Scotch towns. The annual rate during the week under notice was equal to 18 9 in Dublin, 12·1 in Belfast, 25·3 in Cork, 16·8 in Londonderry, 28·7 in Limerick, and 17·5 in Waterford; the mean annual death-rate in the 16 smallest of these Irish towns in the week under notice was equal to 16·4 per 1000. The 371 deaths from all causes in the 22 town districts in the week under notice showed a decline of 52 from the number in the previous week, and included 23 which were referred to the principal epidemic diseases, against 23 and 25 in the two preceding weeks; these 23 deaths were equal to an annual rate of 1·0 per 1000, the rate from the same diseases in the 77 English towns being 1·2 per 1000. The 23 deaths from these epidemic diseases in the Irish towns in the week under notice included 14 from whooping-cough, 3 from measles, 3 from scarlet fever, 2 from diarrhœa, and 1 from diphtheria, but not one from enteric fever or small-pox. The fatal cases of whooping-cough, which had been 4 and 6 in the two previous weeks, further rose to 14 in the week under notice, and included 7 in Dublin, 3 in Londonderry, and 2 in Cork. The 3 fatal cases of scarlet fever showed an increase of 2 upon the number in the previous week; 2 occurred in Dublin and 1 in Belfast. The deaths in the 22 towns during the week included 84 which were referred to pneumonia and other diseases of the respiratory system, showing a decline of 62 from the number in the previous week. The causes of 27, or 7·3 per cent. of the deaths registered in the Irish towns in the week under notice were not certified; in the 77 English towns the proportion of uncertified deaths in the week did not exceed 0·9 per cent.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeon: J. C. Ferguson to the *Royal Arthur*. Staff-Surgeons: A. Davidson to the *Pembroke*, for Royal Naval Barracks; J. N. Robertson to the *Diana*, on recommissioning; C. R. Sheward to the *Pathfinder*, on recommissioning; H. H. R. Denny to the *President*, additional, for hospital course; and A. I. Sheldon to the *Britannia*. Surgeons: F. C. Robinson to the *Pembroke*, additional, for disposal; J. A. Thompson to the *King Edward VII.*; H. Stone to the *Vivid*, for Royal Naval Barracks; F. C. Alton to the *Berwick*; F. J. Gowans to the *President*, additional, for three months' hospital course; H. Woods to the *Barham*, on recommissioning; D. Horgan to the *Diana*, on recommissioning; G. R. McCowen to the *Dwarf*, additional, and on recommissioning; W. C. B. Smith to the *Crescent* and to the *Tamar*; T. R. L. Jones to the *Crescent*, and afterwards to the *Woodlark*; E. J. H. Garstin to the *Crescent* and to the *Nightingale*; F. H. Stephens to the *Crescent* and to the *Kinsha*; R. N. W. Biddulph to the *Doris*, additional; M. F. Caldwell to the *Blenheim*; C. H. L. Petch to the *Indus*; H. M. Langdale to the Royal Marine Division, Portsmouth; S. L. McBean to Portland Hospital; and E. L. Markham to the *King Alfred*, additional, for Devonport Subdivision of Home Fleet.

### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel C. W. Johnson, from Gibraltar, has taken over medical charge of the Military Hospital at Bulford Camp, Salisbury Plain, in succession to Lieutenant-Colonel R. R. N. Moore. Lieutenant-Colonel L. T. M. Nash, from Hyderabad, Sind, has been selected to command the Station Hospital at Karachi. Lieutenant-Colonel P. C. H. Gordon, from Bulford Camp, has taken up duty at Pembroke Dock. Lieutenant-Colonel G. E. Hale, D.S.O., medical inspector of recruits in the Eastern Command, has been selected to command the Station Hospital at Mhow. Major L. P. More, staff officer for Medical Mobilisation Second (Rawal Pindi) Division, has arrived home from India. Major R. F. E. Austin, from Jutogh, has taken up duty at Kasauli. Major W. P. Gwynn has been transferred from Quetta to Karachi. Major G. B. Carter, at present serving in Ireland, has been placed under orders for duty in the Burma Division. Captain C. H. Turner, on return home from a tour of service in India, has been appointed to the Dublin District. Captain A. M. MacLaughlin, from the London District, has taken up duty as Specialist Sanitary Officer to the Scottish Command. Captain A. W. A. Irwin has embarked for tour of service at Gibraltar. Captain H. W. Long has arrived home on duty from Sierra Leone. Captain P. A. Lloyd Jones, from Malta, has been posted to the Irish Command. Captain F. Ashe, from Colchester, has been appointed Specialist in Midwifery and Diseases of Women and Children to the Ninth (Secunderabad) Division. Captain S. C. Bowle and Captain K. A. C. Doig, on completion of a tour of service in India, have been posted to the Southern Command. Captain P. C. T. Davy, from Nowgong, has taken over command of the Station Hospital at Jutogh. Lieutenant T. B. Nicholls has embarked for duty in Egypt. Lieutenant E. C. G. M. Kinkead has been transferred from Kilworth to Buttevant. Lieutenant A. N. R. McNeill, from Ayr, has taken up duty at Mauritius. Lieutenant C. H. O'Rorke has been transferred from the Curragh Camp for duty at Newbridge. Lieutenant G. S. Parkinson, from Dunree Camp, has joined at Enniskillen.

### INDIAN MEDICAL SERVICE.

Lieutenant-Colonel H. P. Dimmock, Bombay, has arrived home. Lieutenant-Colonel R. H. Castor, on return from leave, has been appointed to the Civil Medical Charge at Shwebo, Burma, in succession to Lieutenant-Colonel F. J.

Dews, who has been granted leave combined with furlough for two years. Lieutenant-Colonel J. A. Cunningham has taken over duty as Inspector-General of Civil Hospitals in the United Provinces. Lieutenant-Colonel D. T. Lane, civil surgeon at Muree, has been appointed Civil Surgeon at Lahore, in succession to Lieutenant-Colonel H. Hedley, who has been attached for special duty to the Principal Medical Officer, Second (Rawal Pindi) Division. Lieutenant-Colonel J. A. Burton, Madras, has been granted leave from Dec. 6th. Lieutenant-Colonel A. C. Younan, in medical charge of the 25th Punjabis, has arrived home on leave from Rawal Pindi. Major P. St. More has been appointed Civil Surgeon and District Plague Medical Officer at Attock. Major E. F. E. Baines has been appointed to the substantive Medical Charge of the 3rd Sappers and Miners at Kirkee, in succession to Lieutenant-Colonel G. E. Fooks. Major T. W. Irvine has been appointed Civil Surgeon at Peshawar by the Foreign Department of the Government of India, vice Captain N. M. Wilson, who has been selected as Agency Surgeon at Meshed. Major J. Penny has had an extension of his leave on medical certificate for six months. Captain T. F. Owens, at present on general duty in the chemical examiner's department at Calcutta, has been selected to succeed Major F. N. Windsor as Chemical Examiner at Rangoon. Major S. Browning Smith has been re-posted to the Punjab by the Home Department. Major T. A. O. Langston, Bengal, has been granted leave of absence from Dec. 12th. Captain V. B. Green-Armytage, on return from leave, has been appointed Specialist in Midwifery and Diseases of Women and Children to the Burma Division. Captain G. Fowler has been appointed to the Civil Medical Charge of the Akola District. The services of Captain R. A. Chambers have been replaced at the disposal of the Government of India in the Home Department.

APPOINTMENTS ON H.E. THE VICEROY OF INDIA'S PERSONAL STAFF.

Lord Hardinge, the new Viceroy of India, has made the following appointments to his personal staff:—As Honorary Surgeons: Surgeon-General P. H. Benson, I.M.S., Surgeon-General with the Government of Madras; Surgeon-General A. T. Sloggett, C.B., C.M.G., A.M.S., Principal Medical Officer, (Sixth) Poona Division; Colonel R. H. Forman, A.M.S., Principal Medical Officer, Bombay Brigade; Colonel C. F. Willis, I.M.S., Officiating Deputy Principal Medical Officer, His Majesty's Forces in India; Colonel G. F. A. Harris, I.M.S., Inspector-General of Civil Hospitals in Bengal; Lieutenant-Colonel B. M. Skinner, M.V.O., R.A.M.C., commanding the Station Hospital at Peshawar; Lieutenant-Colonel H. N. Thompson, D.S.O., R.A.M.C., commanding the Station Hospital at Lucknow; Lieutenant-Colonel R. S. F. Henderson, R.A.M.C., Secretary to the Principal Medical Officer, His Majesty's Forces in India; Lieutenant-Colonel H. Smith, I.M.S.; Major B. Seton, I.M.S., Secretary to the Director-General, Indian Medical Service; and Major W. Selby, D.S.O., Civil Surgeon at Lucknow.

SPECIAL RESERVE OF OFFICERS.

*Royal Army Medical Corps.*

Lieutenant Charles J. Simpson is confirmed in his rank.

TERRITORIAL FORCE.

*Royal Army Medical Corps.*

South-Eastern Mounted Brigade Field Ambulance, Royal Army Medical Corps: Major Percy C. Burgess to be Lieutenant-Colonel (dated Nov. 24th, 1910).

1st South Midland Mounted Brigade Field Ambulance, Royal Army Medical Corps: William Henry Cusack to be Lieutenant (dated Sept. 3rd, 1910).

2nd Home Counties Field Ambulance, Royal Army Medical Corps: Major Albert R. Henchley to be Lieutenant-Colonel (dated Nov. 26th, 1910).

3rd West Lancashire Field Ambulance, Royal Army Medical Corps: Captain Henry Dodgson resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Jan. 4th, 1911).

*Attached to Units other than Medical Units.*—Lieutenant Ivan C. Keir resigns his commission (dated Jan. 4th, 1911).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

With the January issue the *Journal of the Royal Army Medical Corps* enters upon its sixteenth volume. In the opening article on Table Jellies Major W. W. O. Beveridge, D.S.O., after remarking that jellies appear to be prescribed for no definite purpose other than that they offer a welcome change in convalescence, points out that jellies have a certain real, though limited, function in health and disease. They are a protein sparer, greater even than the fats or carbohydrates. The author also quotes an American authority Dr. T. R. Martin, who states that "besides its protein-sparing properties, the power to utilise gelatine depends also on the protein condition of the organism at the start; the lower the condition the more strongly does the organism lay claim to gelatine as a means of protecting its living substance." After arriving at the conclusion that it is not at all necessary to wait for early convalescence before giving jellies in most disorders, Major Beveridge discusses the various forms in which jellies can be obtained, their use, and analysis. Lieutenant-Colonel R. J. S. Simpson, C.M.G., has in this number a further instalment of his Medical History of the South African War, and among other useful articles are those on the Incineration of Human Excreta, by Lieutenant-Colonel Bruce Skinner, M.V.O.; and an Inquiry into a Small Epidemic of Paratyphoid Fever in India, by Major H. W. Grattan and Major D. Harvey. Some Episodes in the Life of James Goodall Elkington, an Army Surgeon in the Peninsular Days, together with Extracts from his Journal, by Lieutenant-Colonel H. P. Elkington, will also be found to be of much interest.

THE MILITARY SURGEON.

The December number of the *Military Surgeon*, published in Washington, D.C., contains some interesting material. An address by the President of the Association of Military Surgeons of the United States deals with the status of the Medical Corps of the National Guard in its relation to the Army, the Navy, and the Public Health and Marine Hospital Service, and generally explains the status of the organisation of the Association of Military Surgeons in the United States, of which Colonel K. Weaver is President. Among other articles we may mention as very interesting one by Colonel Nicomedes Antelo, Chief of the Surgical Service at the Military Hospital at Buenos Aires, on the use of tincture of iodine in the surgery of war. The writer comes to the conclusion that this tincture is the ideal skin antiseptic in military surgery, a conclusion which will be seen to be much in accord with the teaching of an article published in our issue this week on the use of iodine as a disinfectant of the skin before operation by Mr. Willmott Evans.

"Audi alteram partem."

## A METHOD OF SERUM DIAGNOSIS FOR TUBERCLE.

*To the Editor of* THE LANCET.

SIR,—I have read with much interest the communication from Captain V. B. Nesfield on a method of serum diagnosis for tubercle which appeared in your columns on Dec. 31st last, inasmuch as I have been experimenting on very similar lines for a long time. The results which I have obtained will be dealt with at length in my Hunterian lectures in February next. I should like, however, to give an outline of my methods and some of my results in view of the fact that Captain Nesfield's method is somewhat similar to mine and might be taken as anticipating it.

There is, of course, nothing new in the attempt to diagnose tuberculosis by means of the method of fixation of complement, a large number of papers on the subject having been published during the last few months. I may refer especially to the researches of Calmette, Massol and Breton, Simon and Hans, Slatineano and Danielopol, Laub and Novosky, Butler and Mefford, Pickert, and others. In most (I believe in all, but have not all the references by me as I write) tuberculin has been used as the antigen, and my earlier work was carried out on similar lines. I find, however, and in this point only does my method resemble that of Captain Nesfield, that an emulsion of killed tubercle bacilli is greatly superior in this respect. But I attach the very greatest importance to a point that he does not mention—the accurate standardisation

of the emulsion. I have used a suspension which when centrifugalised until the deposit is of constant volume in a graduated tube is found to contain 4 per cent. of bacillary substance. I had hoped by this process to obtain an antigen of uniform strength, no matter what the source of the bacilli; this is not quite the case, small deviations being found with different samples of bacilli, and I now find it advisable to test all fresh emulsions against two or three known sera. The standard emulsion keeps fairly well, but I think it gets slightly weaker after six weeks or so; certainly most of my negative results in tuberculous cases have been got when I was using an old emulsion. The necessity for accurate standardisation is very great. Almost every serum will give complement absorption with an emulsion of tubercle bacilli if the latter is sufficiently strong, and, strange as it may seem, the few exceptions are always from tuberculous cases. They are due, as I shall show, to the presence of a substance which has the remarkable property of inhibiting the combination which usually occurs when antigen, antibody, and complement are present. This substance I believe to be the cause of the negative phase.

The criterion as to the strength of the reaction which I have adopted after much preliminary work is the *time necessary for the complete absorption of all complement* when the serum and emulsion are mixed in certain proportions (1 : 4) and incubated. I test the absorption by the addition of sensitised human corpuscles, as in my method for the Wassermann reaction.[1]

I may summarise some of my results. In health the absorption time is about 15–25 minutes. Thus, in 26 healthy persons or non-tuberculous patients 21 have shown times between those figures. In tuberculous patients the time is as a rule greatly shortened. Out of 40 cases tested the absorption time has been under 2½ minutes (it is not practicable to test at a shorter period) in 16 cases, under 5 in 26, under 10 in 31. The sera giving complete absorption in less than 2½ minutes have been tested in some cases with dilutions of the standard emulsion; thus, in one case the absorption time with a 1 in 500 dilution was 10 minutes. This refinement is hardly necessary for diagnostic purposes, but is required when the result of treatment has to be followed.

As regards the indication of the reaction from the point of view of making an immunity index, as Captain Nesfield suggests, I do not think this is altogether possible; immunity in tuberculosis depends on too many factors, especially, as I believe, on the resistance of the tissues. In general terms, however, I agree with him in thinking that, on the whole, the prognosis is good when the serum contains a large amount of antibody, and therefore (as I should put it) has a short absorption time. I have seen patients improve on a shortening time and *vice versâ*. But this is not an invariable rule, for I have found, on repeated examinations, a very long absorption time in a very mild case which was doing well on tuberculin treatment. But I believe it will be found that a prolonged absorption time does indicate a very high degree of susceptibility to the action of tuberculin, and is an indication to give very small doses, though it does not necessarily indicate that the patient's disease is progressive.

Although my method is not an absolute one, I believe it to be the best method for the serum diagnosis of tuberculosis which we have at present; it is simple and easy to carry out, and has the great advantage over the opsonic method of not involving the tedious and eye-destroying counting. It gives positive results in a larger number of cases than does the opsonic method if a single observation only is made, and is less open to technical errors. In one case I was able to demonstrate the negative phase by my method when the opsonic method was entirely useless. I ought to add that I do not think it possible that an absolute method for the serum diagnosis of tuberculosis will ever be invented. Normal persons all contain some amount of antibodies to the tubercle bacillus (this is true, at least, for town dwellers), and, as my method demonstrates with absolute clearness, the amount present in tuberculosis may be the same, or so nearly the same as only to be detected by the most refined quantitative work, or may even be less. The antibodies present in normal blood may be in part the cause of the immunity which most persons possess to the disease. It would be interesting to compare the amount present in adults and in young infants, but this I have not been able to do.

I am, Sir, yours faithfully,

King's College Hospital, Jan. 2nd, 1911. W. D'ESTE EMERY.

[1] THE LANCET, Sept. 3rd, 1910.

## THE POSITION OF HOMŒOPATHY.

*To the Editor of* THE LANCET.

SIR,—Any appeal from Dr. R. Farquharson on a point of medical ethics or professional conduct is, all will admit, well entitled to careful and respectful consideration, and it may therefore be taken as certain that the letter from his pen which appeared in your issue of Dec. 24th, will lead more or less widely to the self-examination which he advises, and which, moreover, is by repute especially appropriate and salutary at this juncture of the year. With an earnest desire to seek peace and ensue it, Dr. Farquharson invites us as members of the medical profession to reconsider our attitude towards "homœopathy" and towards those who are "professors" of this "method of treatment." To sharpen our appetites for this task we are told that the homœopathic "professors" are able to treat disease on a "much more scientific principle" than any which we ourselves possess, and presumably it is to the examination of this therapeutic achievement that we are invited to address ourselves. But, most unfortunately, while offering so alluring a prospect, Dr. Farquharson neither defines the "scientific principle" in question nor indicates where an adequate presentation of it may be found; and the difficulty of accepting his invitation is still further increased by his announcement that "the absurd doctrines of Hahnemann have long since been abandoned." What, then, is the "homœopathy" for which a reconsideration is now requested? For, manifestly, an invitation to examine either "absurd doctrines long since abandoned," or a "scientific principle" not yet defined, is not an attractive proposal, and it is to be feared that until he can be more precise Dr. Farquharson will evoke only the scanty response which he anticipates and which, in the midst of an appeal for charity and goodwill, he proposes to interpret as indicative of the defective courage and candour of his professional brethren.

There remain the "professors" of this vague and amorphous "homœopathy," and these, we are told, suffer grievously for "honestly trying to do their duty according to their lights." They are, it seems, "scorned and rejected of men," meaning, presumably, medical men, for surely, unless rumour is strangely at fault, many a proclaimed "professor" finds a ready and not unremunerative welcome among both laymen and laywomen. And when it can be shown that any purpose other than the welcome just described can be served by the adoption by a medical practitioner of a distinctive title announcing a special therapeutic policy, and implying also the fitness of the public to judge of therapeutic policies in general, Dr. Farquharson may possibly succeed in convincing the profession that his "professors" are as "respectable" as he proclaims them to be. In the meantime, I will venture to remind him of the verdict of one for whose memory, I am sure, he entertains the highest respect. "The true physician," wrote the late Sir William Gairdner, "derives his chief claim to that character from his perfect intellectual and moral freedom. ..... It is the misfortune of homœopathy that its votaries, like those of all exclusive sects, can never occupy [this] position." And again, "It is obviously part of the policy of homœopathy ..... to flaunt in the faces of physicians the banner of its exclusive dogma, and to perpetuate the use of nicknames associated with every kind of bitterness." Such was the considered and deliberate decision of a physician who combined in very unusual measure clearness and breadth of outlook with charity and impartiality of judgment. But it may be said that all this applies only to the full-blooded days when homœopathy *was* homœopathy, and long ere its "absurd doctrines" had been "abandoned" for the vague "scientific principle" at which Dr. Farquharson hints and hesitates. Upon which remark there follows the obvious rejoinder, that so great a change having been accomplished in the creed of the "professors," any appeal for readjustment of attitude and amendment of conduct ought surely to be addressed, not to the medical profession, but to those individuals who, although they have "abandoned" the "absurd doctrines of Hahnemann," still

continue ostentatiously to disport themselves in the livery of the sect of which he was the founder.

I am, Sir, yours faithfully,

Harley-street, W., Dec. 26th, 1910. C. O. HAWTHORNE.

## *RE* MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT.

*To the Editor of* THE LANCET.

SIR,—Having received from the Home Office a printed circular addressed to medical referees, containing, *inter alia*, the attached quotation, I had no alternative but to resign at once my appointments to Circuits 40 and 42, including the Bow, Shoreditch, Bloomsbury, and Whitechapel county courts.

The matter is of great interest to the profession and others, as it is clear that no medical referee appointed by the Secretary of State under the Workmen's Compensation Act can in future examine any workman on behalf of either employer or employed. The position can therefore be only held by those having no practice in accident examination.

I am, Sir, yours faithfully,

ALBERT BENTHALL.

Fellows-road, S. Hampstead, N.W., Dec. 30th, 1910.

*Extract from Home Office Circular to Medical Referees.*

It is particularly undesirable that they should act on behalf either of the employer or insurance company, or of the workman in cases in which weekly payments are actually being made; and apart from any emergency, or other quite exceptional circumstances, they should decline to act in such cases.

The Secretary of State desires to impress on referees the necessity of their paying particular attention to these directions.

## THE "WHOLE-TIME" MEDICAL OFFICER OF HEALTH.

*To the Editor of* THE LANCET.

SIR,—May I venture to point out the slightly ambiguous use of the descriptive term "whole-time," as applied to medical officers of health, which occurs in your most valuable review of the Annus Medicus 1910? A medical officer of health who is debarred from private practice is not necessarily a whole-time officer, and if he holds other public appointments he most certainly is a part-time officer. The recent Order of the Local Government Board hardly *encourages* whole-time appointments; it gives security to the whole-timer and the part-timer alike, but it discourages the part-timer from private practice, and offers him instead certain clinical public appointments such as those alluded to in your retrospect. The real effect of the Order will be to establish the part-timer on an impregnable basis of official pluralism.

I am, Sir, yours faithfully,

Barnes, S.W., Dec. 30th, 1910. F. G. CROOKSHANK.

## A LATIN TREATISE.

*To the Editor of* THE LANCET.

SIR,—In examining the Irish medical MSS. in the library of Trinity College, Dublin, I find three copies (more or less imperfect) of a translation of a Latin treatise which begins: "Cum humanae vitae brevitas, teste Hippocrite, ad immensae (*sic*) artis longitudinem vix sufficiat." If any of your readers could help me to identify this treatise I should be very grateful. It deals largely with eruptive diseases, boils, &c., and, to judge from the number of copies, was probably a standard work in, say, the sixteenth century.

I am, Sir, yours faithfully,

Dublin, Dec. 30th, 1910. T. K. ABBOTT.

## THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

*To the Editor of* THE LANCET.

SIR,—The report of the inaugural dinner of this association appears in your issue of Dec. 17th last. We would be much obliged if you will correct the erroneous statements therein contained—viz., "Irish hospitals, excluding the F.R.C.S.I.," and "that Fellows only of the College should be examiners."

The protestation which the association made was against the system adopted by certain English hospitals of excluding from their staff those possessing the Fellowship of the Royal College of Surgeons, Ireland. The resolution passed at the special meeting on Dec. 10th of the Fellows of the College of Surgeons, Ireland, was:—

That the Examiners shall be selected from amongst the Fellows and the Professors of the College

We are, Sir, yours faithfully,

ANDREW CHARLES, R. P. McDONNELL } Hon. Secretaries.

## A SPECULATION ON THE ORIGIN OF CANCER.

*To the Editor of* THE LANCET.

SIR,—I read with great interest and pleasure the Bradshaw lecture on cancer by Sir Alfred Pearce Gould. He gives all facts known at present about cancer and these are well arranged. All I will say about them is—all honour to the workers and more power to their elbows, Sir Alfred Pearce Gould himself included. If I understood him right, he concludes that certain organs (such as the uterus and the breast), on account of frequently repeated periods of great cellular activity, followed by periods of decline and atrophy, get prematurely old ("before the rest of the woman ages") and therefore are specially prone to cancer.

Now, throughout the whole animal world we find that the older the tissue the less is its cellular activity. Cancer is increased cellular activity. If Sir Alfred Pearce Gould is right, this increased cellular activity takes place in tissue that has grown prematurely old ("before the rest of the woman ages"). It is admitted at once that this increased cellular activity results in disorderly growth; but that is a matter of secondary importance. Thus Sir Alfred Pearce Gould has (1) not stated how cancer originates; and (2) has brought in the field a still more difficult problem—viz., increased cellular activity in tissues prematurely old (thus going against the universal law stated above). But taking the facts thus far known and putting aside for the time being the parasitic theory (and appearances are against it) I humbly beg to state that another explanation is possible.

To begin with, then, the statement often made—that the human body is a machine, timed to go for a certain number of years, after which it gets worn out and thus dies—is not in accordance with facts. Arrangements are made in the body for a constant supply of nutrition to all parts, more than making up for any wear and tear that might take place. Arrangements also are made for immediate removal of all waste materials. Now, if wear and tear had anything to do with old age and death, we ought to have some signs of this during the period of greatest activity. The child is always on the go; the youth is always about and active; but they show no signs of wear and tear. The heart and respiratory muscles do more work than any other part of the body, but we find no signs of extra wear and tear in them. Conclusion: There is nothing to show that old age is brought on by wear and tear of tissues.

Wear and tear of tissues not being able to account for old age, we are obliged to fall back on nutrition. Failure of *suitable* nutrition can be the only other cause. Now, it appears that the tissues, very soon after first coming into existence, begin slowly to change (proteins are unstable). All the time the tissue is changing the nutrition is, comparatively speaking, at a standstill. Thus, what was perfect nutrition at one time becomes less and less perfect as time goes on; and thus is brought about the gradual failure of nutrition. The make of the body is perfect, but no arrangement exists to modify the nutrition in accordance with the changing tissues. Under normal conditions all the tissues march together (change) in regular order. But under certain circumstances this regularity of the march is broken, and certain tissues fall back (particularly the epithelial tissue). Now, this retarded tissue finds the nutrition provided more suitable than the rest of the tissues, and thus comes into activity. Conclusion: It is the tissue which has aged *less* than the rest of the body which is specially prone to cancer.

Sir Alfred Pearce Gould has very ably pointed out the difference between the orderly growth of the embryo and the

disorderly growth of cancer. Now there is one important difference in the structure of the two which I do not remember reading in the lecture, and which may account for the disorderly growth in cancer. In the embryo, side by side with the ordinary tissue, and in due proportion, there exists an organising tissue—viz., the nervous tissue—which is absent in cancer. On rare occasions this organising element is absent also in the impregnated ovum, and the result is the same disorderly growth that we find in cancer. Do we know of any such instances? I think we do—molar pregnancy. Conclusion: Absence of nerve tissue is probably the cause of disorderly growth in cancer.

I am, Sir, yours faithfully,

H. D. MASANI,

Caterham, Dec. 29th, 1910. Lieut.-Col., I.M.S. (Retired).

## A DISCLAIMER.

*To the Editor of* THE LANCET.

SIR,—With reference to the letter by Professor Harvey-Gibson and others in your issue of Dec. 31st will you permit me to say that there appears to be nothing in my book which attempts to involve them in any responsibility for my statements. I mentioned these gentlemen merely to acknowledge (properly, I hope) the help and encouragement which I have received from them. I alone am responsible for all the statements contained in my book.

These statements depend upon what I believe to be observed facts. If your correspondents will do me the honour to point out exactly where I have been mistaken I shall be glad either to admit my mistakes or to discuss the matter further with them.

I am, Sir, yours faithfully,

Liverpool, Dec. 31st, 1910. H. C. ROSS.

## AN INNOVATION IN THE INDIAN MEDICAL SERVICE.

*To the Editor of* THE LANCET.

SIR,—In making some inquiries about the Indian Medical Service from a friend in that service, I have received the following information which my correspondent has no objection to my sending to you.

The papers in India have recently published the fact that a board is sitting at Simla to discuss the changing of the present military medical system for native regiments by withdrawing the I.M.S. officers from their regiments and starting a station hospital system. That the authorities are in favour of this change is shown by the published speeches of the Director-General and Commander-in-Chief at a recent dinner held at Simla. To discuss the *pros* and *cons* of this question would be extremely lengthy; suffice to say that the majority of I.M.S. officers and officers commanding native regiments, if they were asked their opinions, would register them against the new proposals. The only persons who would seem likely to gain would be the senior I.M.S. officers—men of 20 years' service—who would command the "station hospitals" and draw an extra allowance, saved no doubt at the expense of the juniors, for the Government will allow no extra money for the new system. It is improbable that the scale of pay, entered in the prospectus of the I.M.S. as consolidated pay for an officer in charge of a native regiment, would be diminished. But it is quite common under present conditions for such an officer to have charge of another regiment in addition to his own at an extra salary averaging Rs. 50 per month throughout the year. This allowance would, under the new conditions, be lost, and therefore the consolidated pay should be increased by a corresponding amount.

Another allowance likely to be lost under the proposed system is that for the keep of horses for cavalry officers. Under present conditions an officer below the rank of major receives an allowance of Rs. 60 a month for two horses, or above the rank of major Rs. 90 for the upkeep of three horses. These will, however, be just as necessary under the new system. It would be much fairer in the service as it is now if, instead of some officers being allowed three, some two, some one horse, and some none, all drew Rs. 30 per month for one horse, like all other officers with native infantry; for when one is moved from a cavalry to an infantry regiment, or *vice versâ*, a warrant in many cases cannot be drawn for the carriage of horse by train on the grounds that at one end or the other of the journey he is not entitled to a charger. This is a very severe hardship in the frequent changes of the early years of service.

Another change that it would be desirable to make is the allowance of gratuities or bonuses to officers on retiring after the completion of short periods of service. These bonuses are allowed to officers in the R.A.M.C., £1000 being given on retirement at the end of eight years' service and larger sums for different periods in proportion. Similar proportionate allowances should be made for I.M.S. officers, so that they may retire if they so desire at the end of eight or more years with as little loss as possible. Many I.M.S. officers have elected to stay in military employment; indeed, many must have entered the service because they like the life regimental, with its pleasant good-fellowship and fair certainty of a home settled for four or five years at the time. It is likely that many such would not care to stay under the new system, in which they will no longer "run their own show," but be liable to have for their commanding officer—who writes their yearly confidential reports—a native of India. To such, if the new system be introduced, the possibility of retiring after short periods of service should be allowed without greater loss than can be helped.

Lastly, the improvement in the R.A.M.C. of recent years referred to by the Director-General in his speech can hardly be attributed to the station hospital system of itself, but rather to such factors as the efforts of an eminent civil advisory board who have obtained money which has enabled them to make and equip such splendid modern hospitals as the Millbank, the Connaught, the Cambridge, and the Herbert, and provide a first-class nursing system the members of which are drawn from the best nurses of the London hospitals. The hospitals to be erected in India as part of the I.M.S., if the new system be introduced, are to be run without further Government grants.

The above remarks of my correspondent appear to me to be based with fairness upon a common-sense knowledge, and I recommend their consideration to those thinking of entering the service.

I am, Sir, yours faithfully,

London, Dec. 20th, 1910. X. Y. D.

## WHY?

*To the Editor of* THE LANCET.

SIR,—It is said that the report of Admiral Sir John Durnford's Committee on the Naval Medical Department is only kept back till the Treasury has given its sanction to the financial proposals therein. From this we might conclude that the Admiralty proposed to give costly benefits to its medical officers. Yet it does not seem eager to give them benefits which cost it nothing. Another Honours List has appeared without any decoration for any officer of the Naval Medical Department. These honours cost the Admiralty and the country nothing, but exalt the lucky recipient and his brother officers. Unless it is just this encouragement the Admiralty fears, why can it not secure the same marks of appreciation for its officers that the War Office and India Office can get for theirs? Is the Admiralty careless of its medical officers, or is it jealous of them? In either case the Admiralty had better note that the other Services which deal more considerately with their medical officers have competition for the commissions they offer.

I am, Sir, yours faithfully,

Jan. 2nd, 1911. PUZZLED.

## THE REBATE TO PRACTITIONERS ON THE PETROL TAX.

*To the Editor of* THE LANCET.

SIR,—Medical men using cars for their work are entitled to a rebate of 3*d*. per gallon on petrol used for that purpose up to December, 1909. After that date half this rebate is due to them. In December, 1909, I began to apply for my rebate. There was considerable delay, so I wrote to Somerset House. Then the excise officer called upon me and I got a form to fill up. After further letters I was told that I must get certificates from the dealers that the duty had been paid by them. About April I was informed that all was in order.

After another interval I was told that I must begin all over again, with a fresh form and certificates. About the middle

of the summer I was told that all was again in order. Now my letters receive a belated reply that the matter is having attention. It appears useless to apply for the 1910 rebate while things are like this. I should be glad to know if other medical men have obtained their rights for 1909 yet.

I am, Sir, yours faithfully,

Dec. 30th, 1910. MEDICAL MOTORIST.

## RECENT PLAGUE OUTBREAKS IN RUSSIA AND THE FAR EAST.

FROM THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.

*Plague in Odessa and Neighbourhood.*

FURTHER statistics have now been published of the plague epidemic in Odessa, the appearance of which was recorded in my last letter.[1] They are as follows: Between May 22nd and 26th, 1 case, 1 death; between July 5th and 10th, 1 case, 1 death; then, in successive weeks—

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Week ending July | 17th | ... | 6 | cases, | 2 | deaths. |
| ,, | ,, | ,, | 24th | ... | 10 | ,, | 0 | ,, |
| ,, | ,, | ,, | 31st | ... | 17 | ,, | 3 | ,, |
| ,, | ,, | August | 7th | ... | 17 | ,, | 3 | ,, |
| ,, | ,, | ,, | 14th | ... | 16 | ,, | 7 | ,, |
| ,, | ,, | ,, | 21st | ... | 12 | ,, | 1 | ,, |
| ,, | ,, | ,, | 28th | ... | 17 | ,, | 6 | ,, |

bringing the totals, down to the last-named date, to 97 cases and 24 deaths. By Oct. 23rd the figures had reached 132 cases and 39 deaths, and a few cases were still occurring weekly, at least until quite recently. Early in September it was reported that a student in the University of Odessa had contracted the disease, apparently in connexion with laboratory work. Down to Sept. 14th all the cases had been of the bubonic type; on that date the first pneumonic case was seen; it was fatal, but was apparently not succeeded by others.

Towards the end of October the first case of the disease outside Odessa was seen. On the 27th of that month a woman and a child aged 8 years were found to be ill with plague in the village of Roxolani, 32 versts from Odessa. The patients were related, but lived in different houses; the infection was apparently brought from Odessa by a third person, related to both. This person himself returned to Odessa and died there from plague. It is thought that as early as Oct. 19th the infection was already in the village, as on that day two fatal cases of an unknown disease occurred there. The village is a large one of some 3000 inhabitants.

*Plague in the Kirghiz Steppes.*

The infected centres in the Astrakhan government, mentioned in my last letter, seem to have remained free from the disease since the dates there given. But in July plague appeared in the Asiatic province of Semiretchinsk; in two villages of the Atbashin quarter, in the Prjevalsk district of that province, there were 17 cases of pneumonic plague, all fatal, between the end of July and August 11th. Since then no further information has been published respecting this outbreak. In the Uralsk government, in the "5th village" (*sic*) of the Jambeitinsk district, there were 7 cases of plague, with 3 deaths, between August 10th and 14th. No further cases occurred subsequently.

*Plague in Manchuria.*

A serious epidemic of plague has recently prevailed in Manchuria. A telegram of Oct. 14th reported that on the 13th there had been 9 deaths, and on the 14th 17 cases with 4 deaths, from pneumonic plague in a village near the "Manchuria" station (on the Manchuria-East China Railway). The newspapers later reported that 4 deaths from suspected plague had occurred in the village of Akurai in the district of Tchita. About the same time the military governor of Transbaikalia announced that on Oct. 13th and 14th 28 cases of suspected plague had been seen among Chinese in the settlement round the station of Manchuria. By the 24th the totals in this settlement had reached 81 cases and 73 deaths. Apparently all the cases were of the pneumonic form, and all occurred among Chinese with the exception of two—a Russian *feldsher* and a sanitary employee. A telegram from Kharbin, dated Oct. 26th, stated that 9 Chinese had died from the disease at the mines of Tchalainor on the 24th. Sanitary commissions had been formed, it was stated, on the line between Kharbin and Manchuria.

It is further stated that the first cases in the above-named village of Akurai occurred in the family of a man who hunted *tarabagans*, or marmots—the animal which, as is now well known, is extremely liable at certain seasons to suffer from a disease closely resembling plague, and highly infectious to man. From time to time, in the columns of THE LANCET, I have summarised practically all that has hitherto been published with regard to this "*tarabagan* disease." The recent cases in the village of Akurai are held, it is said, to show clearly that the animal disease and human plague are in fact identical diseases.

The latest news from these centres is as follows: In the week ending Oct. 28th there were 4 cases of plague at Dauria station, 2 at the Tarbagatai mines, near Petrovsk, 34 at the station of Manchuria, and 25 deaths at the last. On the 27th a Chinese coming "from the West" died from the disease at Kharbin. Down to Nov. 1st there had been in all, at the station of Manchuria, 184 cases with 166 deaths among Chinese, and 4 cases, all fatal, among Russians. On Nov. 2nd there were 14 suspicious cases at Kharbin, and 3 certain cases, with 1 suspicious, at the Tchalainor mines.

(All the dates mentioned in the above letter are according to the old style, or 13 days behind Western European dates.)

Constantinople, Dec. 10th, 1910.

[1] THE LANCET, Oct. 29th, 1910, p. 1310.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

*Board of Guardians.*

AT a meeting of the board of guardians on Dec. 21st, 1910, an important report from the infirmary management committee was presented. It recommended the establishment of a pathological and bacteriological laboratory and X rays department. The laboratory was required to make examinations of sputum, blood, and products of disease. It would also be required for the preparation of vaccines. The pathologist would make post-mortem examinations. It was estimated that a competent man, living out, to give his whole time to the infirmary, would require a remuneration of £250. The only alternatives were to send to the University or to omit this important factor from the work of the infirmary. The X ray department would be chiefly valuable for the diagnosis of internal diseases, such as stones in the kidneys and ducts, morbid conditions of the abdomen and chest, and small lesions. It would also be of value for the treatment of ringworm, lupus, rodent ulcers, &c. It was thought that an operator could be engaged to attend at the infirmary as required for about £50 per annum. Mr. Darby, in presenting the report, pointed out that investigations had taken place in order to ascertain the class of patients with whom they had to deal. There were about 4000 cases coming to the infirmary every year, and of these 3000 could be classed as ordinary hospital cases—cases for whom the alterations suggested would provide. The objection to sending specimens to the University was that the medical men referring cases wanted results more quickly than was possible if the specimens were sent there for examination. It was also important that the examinations should be made by the man who took the specimens. After some discussion it was agreed to postpone decision on the matter until the next meeting.

*Hospital Sunday Fund.*

At the annual meeting on Dec. 20th, 1910, the statement for the year was presented. This showed that the sum of £6168 0*s.* 6*d.*, the total of the year's collection, was the largest amount ever raised by the fund. This result was attained by a special donation of £1250 given by Colonel Howard Wilkinson, chairman of the General Hospital, for the endowment of a bed. Apart from that donation, the amount was practically the same as last year. The honorary secretary, Mr. F. Impey, directed attention to the growing tendency on the part of some churches to set aside a portion of the collections for the purchase of tickets for their own

distribution instead of handing over the whole amount to the fund. If this developed it would undermine the whole system upon which the collection had been built up. They overlooked the fact that the money provided by the Hospital Sunday Fund had, ever since its inception, been a free gift. If it had not been for this fact the hospitals could not continue to treat, as they did, absolutely free of cost, and in the greater number of cases without recommendations, those people who were unable to pay for treatment. The apportionment of the collections, exclusive of special donations, is as follows:—£1258 to the General and Queen's Hospitals; £125 16*s.* 1*d.* to the General Dispensary, Children's, and Eye Hospitals, Deaf and Dumb and Blind Institutions; £88 1*s.* 3*d.* to the Women's, Homœopathic, Orthopædic and Spinal hospitals, the Birmingham Sanatorium, District Nursing Society, and Lying-in Charity; £54 10*s.* 4*d.* to the Skin and Urinary and Ear and Throat Hospitals and the Moseley Convalescent Home; and £12 11*s.* 6*d.* to the Dental Hospital.

*First Southern General Hospital, T.F.*

Lieutenant-Colonel Jordan Lloyd presided at the annual supper on Dec. 17th, 1910. The prizes won by the men during the year were presented by Colonel W. P. Whitcombe. Lieutenant-Colonel Barnsley, in proposing the toast of "The First Southern General Hospital," said that three years ago a skeleton was produced by Mr. Haldane, and he was proud to know that in that division at least it had been clothed with flesh, and in no department so strikingly and successfully as in the medical. He congratulated Colonel Whitcombe that so much had been accomplished in such a short time and with such attention to detail. One could not help appreciating the patriotism and devotion of those eminent members of the medical profession in Birmingham who had supported the work, and were doing their best to see that should the need arise they would be found thoroughly efficient. Lieutenant-Colonel Lloyd, in responding, said that they had entered on the movement solely with the desire to do their best for their country and their fellow men. The First Southern General Hospital was in a state of efficiency. A great amount of practical work had been carried out during the past year, and they had arrived at such a point that they were prepared to deal with anything that might happen at short notice. They were ready even if the country were invaded next week.

Jan. 2nd.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*University of Liverpool: Medical Students' Annual Dinner: The New Associate Professor of Pathology.*

THE annual dinner of the students of the medical school was held at the Exchange Hotel on Dec. 17th last. Mr. R. W. Murray, surgeon to the David Lewis Northern Hospital, occupied the chair, Dr. E. E. Glynn filling the vice-chair. A large number of the staff of the united clinical School were present, as also were guests from the medical schools at Manchester and Leeds. The dinner proved a great success, topical songs adding to the enjoyment of the repast.—On the recommendation of the Faculty of Medicine and Senate, the Council of the University has conferred the title of "Associate Professor" upon Dr. Glynn. For the last six years Dr. Glynn has been lecturer in pathology at the University, and has proved a valuable assistant to Sir Rubert Boyce, the professor of pathology.

*Medical Men and Medical Certificates: A Committee's Grievance.*

At the last meeting of the Runcorn education committee the chairman stated that it was a common practice for medical men, when certifying that a child was unable to attend school, to neglect to fill in the nature of the illness on the certificate, although the teacher was required to fill in an elaborate form, supplied by the county council, stating the nature of the illness. He mentioned that some of the medical men resented being asked the cause of the illness. He thought it should be made known that the request was necessary, and not the mere caprice of a teacher. Mr. Redman (county inspector) said this was an old-standing trouble. In some places practitioners had taken a very strong line with regard to it. They would not state what the illness was on principle. The present arrangement was not satisfactory. It was resolved to write to the medical men asking them to fill in the certificates.

Jan. 3rd.

## LEEDS.

(FROM OUR OWN CORRESPONDENT.)

*The General Infirmary and Multiple Appointments among the Staff.*

IN an annotation in THE LANCET of Dec. 17th, 1910, headed "Pluralism and the Leeds General Infirmary" reference is made to the recent passing of certain rules restricting in some measure the holding of other hospital appointments by members of the honorary staff. Teaching appointments at the university and consulting appointments at other hospitals, of course, are not touched by this restriction, but members of the full staff must not hold any other hospital appointment, and members of the assistant staff may not hold more than one other hospital appointment, which, however, must not involve the charge of beds. In a leading article in THE LANCET of Dec. 24th on Pluralists in Medical Posts these rules are commented on with favour as follows: "The rules display very clearly the modern feeling towards pluralism in medical appointments, and are wise in their different treatment of the full and assistant staffs." The object of this further reference to the subject—of which the report, so far as it goes, is quite correct—is to point out that the changes were made not solely at the instigation of the lay members of the board, but after a full discussion of the whole matter by the weekly board, which in Leeds, happily, consists not only of the annually elected lay members but also of all the members of the honorary staff, from the senior consultant to the junior assistant. The voting power of the honorary staff is very properly limited to eight votes so as to leave the ultimate verdict, in the event of a purely party vote—an occurrence as yet unknown—in the hands of the lay members. Every member of the honorary staff therefore had an opportunity of discussing the matter and most of them did so, and the ultimate recommendation of the rules to the general meeting of the subscribers was carried without opposition from the members of the staff, by whom the alterations were almost unanimously approved. The bare announcement of an alteration in rules, carrying with it, as these do, some interference with the freedom of the members of the staff, might imply some discontent on the part of the board of management and raise visions in the minds of those not acquainted with the happy relations which have always existed in Leeds between the lay and the professional element of an antagonism which does not exist. Nor must the rules be taken purely by themselves—that is to say, without regard to the local conditions, such as the number of other charitable institutions in the city and the existing rules of the infirmary. In the first place, every member of the full staff is already under the conditions imposed by the new rules—that is, holding no other hospital appointment—and is fully of opinion that his position at the infirmary affords full scope for his energies, so far as hospital work is concerned. A recent rule, which applies to the present members of the staff as well as to future members, is that all members of the assistant staff are from the day of their election entitled to the use of a certain number of beds. A restriction as to what duties they may undertake outside the walls of the infirmary is not, therefore, unreasonable. During the discussion of the new rules representations were made by some of the other charities of the city,—namely, by the Public Dispensary, the Hospital for Women and Children, and the Association for the Prevention and Cure of Tuberculosis. It was at once seen, however, that the Hospital for Women and Children would not be injured in any way. The number of patients treated in the wards of the infirmary for diseases peculiar to women calls for all the energies of the honorary officer attached to the department of obstetrics and gynæcology, and, as a matter of fact, the only two occupants of the post resigned their positions at the smaller institution when they were in succession appointed to the infirmary. An honorary physiciancy at the Public Dispensary—a most valuable position—is often held by a member of the assistant

staff of the infirmary, but it has been the custom if any one of the three honorary physicians of the dispensary is appointed to the infirmary for that officer to resign his dispensary appointment in favour of anyone who is not in general practice, and who is therefore eligible for the post. If, however, he is promoted to the full staff of the infirmary before he has severed his connexion with the dispensary, he will, under the new rules, be called upon to do so, but in order that the dispensary may not be inconvenienced it has been arranged that the resignation need not take place until 12 months have elapsed. The only real difficulty arose in connexion with the appointments at the Association for the Prevention and Cure of Tuberculosis, which involves the charge of beds. To meet this special case a new rule is being formulated which will ensure the services of at least one man of infirmary standing. The general terms of this rule have been agreed upon by the board, but as it has not yet been submitted to the general body of the governors it must not be discussed here at present.

Jan. 3rd.

## BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

*Bristol School for Mothers.*

ABOUT a year ago the foundation of a "School for Mothers" in St. Philip's, an East-end district of Bristol, was announced in these columns. The first report, which has just been issued, is a distinctly encouraging record. The school, which has been founded on the lines of the well-known institution in St. Pancras, is open every Friday afternoon in the Broad Plain Girls' Club House. Mothers bring their children for advice as to feeding and such matters, and classes of a simple and practical kind are held. The work is done by a staff of voluntary workers in conjunction with Dr. Annie Cornall. A provident club for women expecting confinement has been started. So far it is not considered necessary to provide dinners for nursing mothers, though a few who are ill-nourished are receiving suitable meals privately in a neighbouring restaurant. Dr. D. S. Davies, the medical officer of health, takes an interest in the work and gives valuable support and help. In the year that is completed 99 mothers have attended the school and the work is expanding steadily.

*Christmas in the Bristol Hospitals.*

As usual, Christmas was by no means forgotten in the various hospitals of Bristol. The Christmas-tree celebrations are so arranged that they are held on different days at the different institutions, so that the public is enabled to allot its moral and financial support evenly. This year Miss Hayes, the Lady Mayoress, acted as distributer of presents at the Royal Infirmary, while Lady Howell Davies and Mrs. T. C. May performed a like office for the General Hospital, and the Hon. Mrs. Irby at the Children's Hospital.

*Bristol University Colston Society.*

The twelfth annual dinner of the Colston Society is to take place on Monday, Jan. 16th, in the large hall of the University. Sir Alfred Hopkinson, Vice-Chancellor of the Victoria University of Manchester, will be the guest of the evening. The circular letter from the President, Mr. J. H. Howell, announcing this, states that the society wishes to raise its annual contribution to the University funds from £450 to £1000; to this end he appeals for new subscribers and larger subscriptions. The society proposes to establish a University Colston Fund for industrial, agricultural, and public health research, to be administered by a committee representing the society and the University Senate, which shall decide on the scope and direction of the grants to be made. Such work would, of course, be carried on within the precincts and under the auspices of the University.

*The Bristol General Hospital.*

Lord Winterstoke has given £5000 to the special fund which is being raised for the extension of the Bristol General Hospital.

*Interesting Function at the Bridgwater Hospital.*

After the annual meeting of the subscribers of the Bridgwater Hospital, which was held on Dec. 21st last under the presidency of Mr. E. Jardine, M.P., Mrs. Jardine unveiled in the hall of the institution two memorial brasses which have been erected in memory of the late Dr. W. L. Winterbotham and Dr. F. J. C. Parsons, two members of the honorary medical staff. Mrs. Jardine afterwards uncovered a bust of the late Dr. Jonathan Toogood, who founded the charity about a century ago.

*New Isolation Wing for the Weston super-Mare Hospital.*

On Dec. 20th last a new isolation block, which has been recently added to the Weston-super-Mare Hospital, was formally opened in the presence of a large gathering. The building contains two wards, each of which will accommodate two patients, and a nurse's room, bathroom, kitchen, &c., have also been erected. The cost of the undertaking has been over £1500, and this sum has been generously given by Mr. R. H. Hooker of Weston-super-Mare.

*District Medical Officers and Old Age Pensioners.*

Some discussion has recently taken place in reference to the duties of district medical officers and the attendance of old age pensioners. At the last meeting of the Tavistock (Devon) board of guardians it was reported that some of the district medical officers were prepared to attend old age pensioners without any application being made through the relieving officer, whilst others stated that they should require orders from the relieving officers.

*The Devon and Cornwall Sanatorium for Consumptives, Didworthy.*

At a recent meeting of the committee of the Didworthy Sanatorium it was stated that the council of the King Edward's Hospital Fund for London had allocated £875 to the institution on the condition that 10 beds should be reserved during 1911 for patients from the London Hospital, Guy's Hospital, and the City of London Hospital for Diseases of the Chest.

Jan. 3rd.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*The Local Government Board and Dairy Inspection.*

A FEW weeks ago, as recorded in THE LANCET of Nov. 19th, 1910, p. 1519, the King's Bench Division unanimously refused the application of the Local Government Board for a *mandamus* directed to the Kilmallock rural district council ordering the council to obey the Order of the Local Government Board regarding the appointment of a veterinary surgeon as inspector of dairies and cowsheds. Last week the Court of Appeal, consisting of the Lord Chancellor, Lord Justice Holmes, and Lord Justice Cherry, unanimously reversed the decision of the King's Bench and directed the order of *mandamus* to issue. Lord Justice Holmes, in a reasoned judgment, held that the Dairies and Cowsheds Order, 1908, was not *ultra vires*, and also that it was within the power of the Local Government Board to define the qualifications of the inspector to be appointed, as it had done in this case—namely, that he should be a qualified veterinary surgeon. Lord Justice Cherry was not quite confident of the validity of the Dairies and Cowsheds Order, but thought it a question which the court was not called on to decide. I have not heard whether the Kilmallock council intends to take the matter further. If not, the Local Government Board is likely to proceed to enforce the Order on all the councils which up to the present have remained obdurate. It was stated in court that no less than 156 local authorities had already acted on the Order.

*Old Age Pensions and the Poor-law.*

With the end of the year 1910 the pauper disqualification is removed as regards the eligibility for old-age pensions. This week, therefore, will see a large increase in the number of pensioners. Practically the whole body of old people in receipt of out-door relief will exchange such relief for the State pension. Out-door relief rarely exceeds a couple of shillings a week, with a certain stigma attached. Of the old people in workhouses, however, a much smaller proportion than was expected will claim discharge and a pension. Poor-law guardians all over the country are much surprised at the unwillingness of the old people in their care to leave the shelter of the workhouse. One board, indeed, has decided to dismiss all inmates entitled to receive a pension—a proceeding of more than doubtful legality.

*Water-supply of Western Watering-places.*

One of the chief causes of the comparative failure of Irish seaside resorts to attract the favour to which their natural surroundings entitle them lies in a defective water-supply and drainage. Last season much alarm was caused among visitors to Bundoran, a beautiful village in Co. Donegal, by the report of an outbreak of typhoid fever, over a dozen cases occurring within a few weeks, and probably many hundred visitors were scared away. Rosses Point, Co. Sligo, suffers in similar fashion. Situated in a beautiful and interesting country, it possesses one of the best golf courses in Ireland, and is easily accessible from Dublin. Though capable of very extensive development, it is without either a trustworthy water-supply or a drainage system. Water is drawn from wells and pumps, and the sanitary receptacles are privies and cesspools. The district medical officer of health, Mr. John Laird, drew attention in his recent reports to the urgency of these matters, pointing out that refuse must percolate into the wells and pumps. Several cases of typhoid fever, with three deaths, have been reported during the past year. Notwithstanding that last year and on many previous occasions Mr. Laird made similar reports the district council has refused to move in the matter.

*Extra Professional Assistance in Poor-law Medical Work.*

By the Local Government Board regulations a Poor-law medical office is entitled, when necessary for purposes of diagnosis or treatment, to summon outside medical aid, the fee to be paid by the guardians. Many boards of guardians frame scales of fees, usually quite inadequate, and seek to impose them on the consultant, who may be unaware of their existence. Recently at Cookstown, Co. Tyrone, Dr. Charles Graves, requiring help late at night in the treatment of severe wounds, summoned Dr. R. Campbell of Belfast, fifty miles away, who motored down, arriving at 2 A.M. After operating he demanded the very moderate fee of 10 guineas. The fee according to the guardians' scale was *one guinea and car hire.* While several guardians denied the medical officer's right to call outside professional assistance unless he could get it at the guardians' scale, the magistrate, with better sense, ordered payment of the fee.

*Knighthood for Dublin Physician.*

In the list of New Year Honours a knighthood has been conferred on Dr. Joseph Michael Redmond.

*Condition of the Irish Primary Schools.*

Considering the deplorable hygienic condition of the primary schools in Ireland it was only uatural that at a meeting of the central executive committee of the Irish Teachers' Organisation, held in Dublin on Dec. 27th, 1910, the following resolution should have been passed:—

> That we beg to remind the Chief Secretary of the urgency of the question of the heating and cleaning of national schools, and request him to immediately see that his promise be redeemed, as all the conditions laid down by the Treasury have been fully complied with.

A very sympathetic letter was read to the meeting on this question of the schools by the Countess of Aberdeen. Mr. Birrell is in the Cabinet, and it is considered his duty to redeem his promise. A man of his weight in the Government could easily, if he set his mind to it, make the Treasury yield on a point so small, yet so vital to the health of the children of Ireland. The first great increase in the tuberculous death-rate in Ireland is coincident with the school age, and that increase grows steadily through the whole period of school attendance.

*Diphtheria in Dundalk.*

At an inquest on an infant held in Dundalk Workhouse on Dec. 27th, 1910, it came out in evidence that, though ill of diphtheria, it had been allowed to remain for eight days without medical attendance. It appeared that the coroner had gone to the trouble of getting paragraphs put in the newspapers warning parents that they should have their children attended to immediately on their showing any symptoms of diphtheria, and he intimated that in any case in future, where a child died from this disease without being attended to in proper time, he would hold an inquest in order to direct public attention to the parents' neglect. It was, he said, scandalous that such a state of affairs as this should exist. A number of children had lost their lives in consequence of this delay, while from the same cause others had had only hair-breadth escapes from death. The head of the police present said that he must take a note of the case mentioned by the coroner, Mr. J. C. Sellars, a medical man, for inquiry with a view to a prosecution under the Children Act for neglect in procuring medical treatment for a sick child.

*The Abbey Sanatorium, Belfast.*

Mr. Robert Hall, visiting physician to the Abbey Sanatorium, which is under the management of the Belfast board of guardians, has just issued his report for the half-year ending Sept. 30th, 1910. During that period 631 patients were under treatment, and of these 366 were discharged or died, an excess of 47 over the number in the corresponding half-year of 1909; while the remaining 265 were still under treatment. Of the patients discharged 34 were greatly improved, 177 improved, 33 not improved, and 30 had not been long in the institution. There were 92 deaths. The duration of treatment in the case of the patients discharged as greatly improved was 302 days for men and 280 days for women; improved, 162 and 123 days respectively; not improved, 143 and 57 days; not long in sanatorium, 9 and 11 days. As to the ages of patients, 6 were under 10 years, 16 were between 10 and 15 years, 60 between 15 and 20 years, 47 between 20 and 25 years, 60 between 25 and 30 years, 45 between 30 and 35 years, 41 between 35 and 40, and between the ages of 40 and 65 there were 143 patients. The youngest patient was 6 and the oldest 68 years of age. As to occupations, there were 19 spinners, 13 schools girls, 10 weavers, 8 servants, 8 stitchers, 6 hawkers, and 100 labourers. For the half-year the receipts were £489 5*s.* 11*d.* and the expenditure £6503 1*s.* 1*d.* The average cost per week of each patient was 13*s.* 9*d.*, which was increased by 3*s.* 6¾*d.* per week, representing the repayment of loans. The slight increase in the total expenditure was due to an increase in clothing purchased during the six months, the other charges being practically the same as in 1909.

*William Smyth, M.D. R.U.I., J.P.*

I regret to announce the death of Dr. W. Smyth at his residence, Banbridge, Co. Down, on the night of Dec. 31st, 1910. A student of Queen's College, Belfast, Dr. Smyth graduated as M.D. of the old Queen's University of Ireland in 1878. After some time spent in England Dr. Smyth returned to his native town in 1880, and there built up an extensive practice. He was medical officer to the Royal Irish Constabulary and to the Post Office. For a time he was a member of the Banbridge board of guardians and of the town commissioners, but failing health (owing to chronic asthma) obliged him to give up these positions. He was a J.P. for Co. Down. Dr. Smyth leaves a widow and six children to lament their loss.

*Health of Belfast.*

The report of the medical officer of health as to the health of Belfast during the period between Nov. 13th and Dec. 17th, 1910, presented at the usual monthly meeting of the city council, held on Jan. 2nd, showed that 212 cases of infectious disease had been notified—viz., 1 of typhus fever, 2 of enteric fever, 149 of scarlet fever, 2 of simple continued fever, 2 of puerperal fever, 34 of diphtheria, and 21 of erysipelas. 80 cases of pulmonary tuberculosis were also notified. The epidemic of scarlet fever has not yet abated, there being 149 cases notified during the month, as compared with 118 in the preceding four weeks. The average annual death-rate from all causes was 17·6, as compared with 15·5 in the preceding month, and 22·7 in the corresponding period of 1909. The number of deaths of children under one year old per 1000 births during 1910 (as calculated on the number of deaths registered during the 50 weeks ended Dec. 17th, 1910) was 144, as compared with 135 in 1909, 147 in 1908, 135 in 1907, and 143 in 1906. The excess-rate is largely due to the number of deaths caused by measles, of which there were 590 registered, being equal to a rate of 1·3 per 1000 of the population, which rate is as high as that registered from zymotic disease during the year 1909.

*Christmas.*

At the various Belfast hospitals and at many of the county infirmaries and union workhouse hospitals in the North of Ireland, the patients were entertained in the usual way, either by the boards of management, or by friends, at Christmas.

Jan. 3rd.

# PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Thermo-anæsthesia in Zona.*

AT a recent meeting of the Société Médicale des Hôpitaux M. Ramond said that from observations made on 43 cases of primary zona at the Hôpital de la Pitié and the Hôpital Saint Antoine he had found that, in addition to the well-known disorders of sensation, there was almost constantly a condition of thermo-anæsthesia which might persist for several months. Half of the cases also presented the condition of bulbo-capillary reflex, or "gooseskin," a phenomenon which could be easily elicited by rubbing the skin of the affected part with the finger-nail. Moreover, in three cases there was glycosuria for periods varying from 7 to 15 days, and in one case there was obvious polyuria with or without frequent micturition, just as in certain forms of sciatica. The best treatment for the pains which outlasted the eruption seemed to be the injection of sterilised air.

*Preventive and Curative Treatment of Beri-beri.*

At the November meeting of the Société de Pathologie Exotique M. Bréaudat and M. Denier reported that in the epidemic of beri-beri which occurred at Cape Saint Jacques from June 1909, to April, 1910, they had treated patients with the outer covering (*son*) of paddy, which corresponded to the bran of European cereals. They came to the conclusion that in this epidemic the disease presented both the dry and the dropsical form with a predominance of cardiac symptoms. The above-mentioned product obtained from paddy did not in general cause any digestive trouble. It was used both for prophylaxis and also as a remedy. For the former purpose it was given in doses of 40 grammes per day, and principally to the detachment of tirailleurs, on whom it had a well-marked protective influence, but in the case of men who were already suffering from the disease it did not seem to produce any effect. Used as a remedy in doses of 40 grammes and upwards, without any other medicinal treatment and without any change in the food given to the natives, its results were identical with those of the numerous therapeutic agents hitherto recommended in association with a European *régime*, while it possessed the advantages over the latter of being simple, cheap, and always obtainable by the natives.

*Foreign Lepers in Paris.*

At a meeting of the same society, held on Dec. 14th, 1910, Mr. Jeanselme gave the results of observations made on 61 cases of leprosy which he had seen in Paris partly in private practice and partly in a hospital. They had come principally from the West Indies, from Guiana, and from Brazil. Of these 61 lepers moving about freely in Paris 38 presented manifest signs of the disease, including purulent rhinitis, bucco-pharyngeal lesions, laryngitis, and leprous orchitis. Of these 38 carriers of Hansen's bacillus 26 were hospital patients but were not properly isolated, and 12 lived at home. The lepers who came to Paris belonged to all classes of society. Those who were financially well off lived in hotels, furnished lodgings, and boarding houses; they engaged servants, and in summer-time they visited mineral water resorts and sea-side bathing places, scattering the germs of infection wherever they went. Some of those in humbler positions were not less dangerous. M. Jeanselme quoted the case of a Jewish pedlar from Constantinople who carried merchandise (and at the same time the bacillus of leprosy) from village to village. Among the 61 lepers there were three school teachers, a valet, and even a nursemaid. The latter, in whom the disease was complicated with rhinitis, had charge of a child 5 years of age in a middle-class family; a fresh development of her symptoms compelled her to pass two years in the Hôpital Saint Louis, and on recovery to some extent she returned to her former employers, who gave her the care of a new-born child. Leprosy is not one of the compulsorily notifiable diseases, but some supervision of such cases is urgently required. Infected children ought to be removed from schools and lepers ought to be prevented from following certain occupations.

*Ehrlich's Remedy "No. 606" (Arsenobenzol) in the Treatment of Diseases of the Nervous System.*

At a meeting of the Société Médicale des Hôpitaux, held on Dec. 16th, 1910, M. Marinesco said that in two cases of cerebral gumma with probable implication of the meninges he had used arsenobenzol with good results, whilst in four cases of syphilitic hemiplegia there was an improvement but in a less degree. In three patients suffering from tabes the shooting pains were relieved; in a fourth case of the same disease in a quite early stage the Argyll Robertson sign disappeared. In a fifth case a superficial perforating ulcer of the sole of the foot healed up in a few days. In six cases of general paralysis there was no perceptible good effect, even when the disease was only just commencing. In two syphilitic patients suffering from early facial paralysis and neuralgia the results were very satisfactory.

*Chronic Poisoning by Carbon Monoxide.*

At a meeting of the Academy of Medicine held on Dec. 19th, 1910, M. Morel and M. Mouriquand gave particulars of a case in which a number of persons attending a laboratory in Lyons suffered from poisoning by carbon monoxide. These individuals, about 40 in number, passed about eight hours in the laboratory every day except Sunday, and 35 of them presented very similar symptoms of illness, the cause of which was at first unknown, but was eventually traced to the presence of abnormal amounts of carbon monoxide in the atmosphere of the rooms, the proportions varying from 1 part in 10,000 to 1 part in 1000. It was derived from numerous leakages of illuminating gas containing between 12 and 14 per cent. of carbon monoxide, as the addition of water gas to illuminating gas is permitted in towns. It proceeded also, but only in winter, from the defective joints of a heating apparatus. The patients suffered from nervous symptoms, digestive troubles, with hyperchlorhydria, and transient albuminuria and glycosuria. The symptoms appeared in winter when the heating apparatus was in use and disappeared with absolute regularity during the periods of vacation.

*The Huchard Bequest.*

Dr. Huchard, who was a member of the Academy of Medicine and whose obituary was published in THE LANCET of Dec. 24th last, has left to the Academy of Medicine a sum of 100,000 francs for the foundation of an annual prize to be called the "Henri Huchard Prize awarded by the Academy of Medicine for devotion to medical duty: In memory of Marcel Huchard." The intention of the testator was to assist students who had either suffered in consequence of their devotion to science or were unable to continue their studies.

Jan. 2nd.

# CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

*The Grievances of the Medical Students.*

THE following two regulations in the new medical programme submitted by the professors of the Medical Faculty to the Minister of Public Instruction have excited keen protest from all the medical students. First, it is enacted that every student must be examined in all the subjects at one fixed period. Second, a student who has failed three consecutive times in one and the same subject will have his name erased from the list of the candidates. Since these two new regulations apply also to the final students, these latter have determined to boycott the Medical Faculty and have unanimously refused to sit for the examinations until the named regulations are modified. I consider that to some extent the students have right on their side. Some of these students have spent in their medical studies six or even seven years and under extremely unfavourable conditions, inasmuch as the teaching and equipment of the Medical Faculty are not of a satisfactory character as yet, and in some ways altogether primitive. To make it possible that a student after seven years' study should lose for ever the results of his labours because he failed three times in one subject seems a most drastic proceeding, a revolution which should not have been attempted in this sudden way. In the military department of the Medical Faculty the position will be still worse under this reforming scheme, as here a student loses his medical career after a second failure in one subject. The students have submitted their unanimous protest to the Minister of Public Instruction, but without attaining any satisfactory result. In their protest they rightly dwell upon the fact that during the old *régime* they could not attend the lectures in a regular way, as owing to the political disturbances the Medical Faculty was closed for months, while a

number of the students were kept in prison for more or less long periods under the suspicion that they adhered to dangerous principles. Modifications in the new programme have been promised to the students as on previous occasions, but it now seems that the authorities do not intend keeping these promises.

*Count Tolstoy: A Personal Reminiscence.*

I had met my great compatriot only once, but to the end of my life I shall remember the profound impression of this meeting. It happened in a train going from Kieff to Odessa. Tolstoy always travelled third class. To be, at least for some short while, in his closer company I changed my ticket and accommodated myself opposite the count in a filthy railway carriage packed with peasants. Tolstoy delighted to mix with these, to converse with them on their needs and misery, and he always did it with that straightforwardness and naturalness which were such pronounced characteristics of the great man. On one station we saw a group of prisoners being despatched to Siberia. Tolstoy left the carriage and entered into conversation with them. Afterwards he made to me the following characteristic remark: "Government and society engender these outcasts and then send them to Siberia, or, still worse, execute them." When I ventured to ask what, then, should be done with such outcasts, Tolstoy answered: "What do you do with sick and diseased and insane persons? And do you really think that these prisoners are worse than those who condemned them?" Tolstoy had some perplexing incongruities of mind. Thus he disliked medical men and he felt an uncontrollable antagonism to Jews. When the latter were persecuted he never raised his mighty voice of protest. Great as he was he could not rise, in this respect, above the general feeling of the fierce Russian antisemitism. As to medical men, he often ridiculed them and their science and never showed any confidence in their treatment. Yet with all that he was undeniably the greatest Russian of his time.

Dec. 29th, 1910.

## VIENNA.

(FROM OUR OWN CORRESPONDENT.)

*The Jewish Population in Vienna.*

IN Vienna there is a considerable Jewish population, the vital statistics of which are fairly well collected by the Board of Health peculiar to these communities within the general community. A report has recently been issued by the "Cultusgemeinde," or board of guardians, from which the following figures may be quoted. In 1909 there were in Vienna 180,000 adherents of the Mosaic law, forming about 9 per cent. of the entire population of the capital. Their increase was 4 per cent. per annum, whereas that of the entire population was only 2 per cent. The influx of Jews from the country was not considerable, but the non-Jewish inhabitants were augmented by immigration. Thus the increase of the Jewish part of the population must be put down to three factors—namely, larger number of births, better care of the infants, and greater longevity. This can be substantiated by a few figures. There were 2502 Jewish children born alive in 1909, so that they increased the numbers of the community by 1·5 per cent., whilst the average increase of population in this city from this source is 1 per cent. The Jewish death-rate was 12·5 per 1000, while the general death-rate for Vienna was 16 per 1000. Only 185 Jewish infants under 1 year of age died in that year, being less than 9 per cent. of the total mortality, or 75 per 1000 births, whilst in Vienna the mortality of infants is 13 per cent. of all deaths, or 129 per 1000 births. That longevity is not infrequent amongst that part of the population is proved by the fact that 30 per cent. of all deaths happened in persons over 65 years of age. There were, for instance, 283 deaths at the age of 80 years, 134 between 80 and 90 years, and 14 deaths between 95 and 100 years. It is interesting to note that at these advanced ages there were more deaths of females than of males. As regards morbidity, leukæmia, diabetes, and neurasthenia were more frequent among the Jews than among their non-Jewish fellow citizens, whilst obesity with its concomitants, gout, rheumatism, and liver disorders, were frequent amongst women. The hospital registers, in which the religion of the patients is always noted, supply no evidence that mental diseases are exceptionally prevalent amongst Jews. On the whole, the report emphasizes the beneficent result of adherence to the religious rules of the Mosaic law and observance of its injunctions respecting food, personal cleanliness, and the care of pregnant women and infants.

*The State Institute for the Care of Mothers and Infants.*

In anticipation of the eightieth anniversary of his birthday the venerable Emperor expressed a wish that the money which was about to be laid out in celebrating that event should be made use of for the benefit of children. The suggestion was immediately followed and a large sum of money has now been collected, from which the Reichsanstalt für Mutter und Säuglingsfürsorge (Institute for the Care of Mothers and Infants) has been organised. The Emperor has graciously consented to be the Protector of the Institute, whilst some of the highest officers of the State hold various honorary positions in connexion with it. The following is an outline of the system according to which the work of the institute will be conducted. Every district hospital will be asked to send two members of its female nursing staff, and these women will at the institute be formed into classes and will receive instruction, lasting from three to six months, in all subjects pertaining to the management of infants. On the conclusion of this instruction the nurses will return to their hospitals. Midwives will also be eligible for these courses of instruction, and as they are very often the principal advisers of young mothers with regard to the upbringing of their families they will have opportunities of combating popular errors and superstitions relative to the first year of a child's life. It is also intended to organise a special order of children's nurses. In Germany and some other countries the necessity of preliminary training for such positions is recognised, but in Austria there is at present nothing of that kind worth speaking of. An important branch of the institute will be the post-graduate classes for medical practitioners who desire instruction in the care of healthy children, as well as for those who wish to qualify for the position of head of one of the branch institutes to be created later in various cities. Classes will also be formed in which women will be taught how children should be fed and brought up. In connexion with these classes there will be "consulting days," on which mothers who can produce evidence of being in necessitous circumstances may bring their infants to the institute, where they will receive advice as to feeding and other problems of health and disease. An important department of the Institute will be a school, in which young persons suffering from either moral, psychical, or physical defects will be received, educated, and taken care of, special attention being paid to feeble-minded children, to those afflicted with hereditary taints, and to sufferers from the after effects of diseases of the brain and nervous system. A staff of specially trained teachers, medical men, and nurses will be constantly at work, and as the practical care of such afflicted children is hardly known here for the lower classes of the population, the necessity for it is really urgent. The system adopted at the institute will provide for the training every year of 20 special children's nurses and 40 midwives and hospital nurses; there will also be accommodation for 40 infants and 20 older children for six weeks each, or 550 children per year. It is estimated that the children will stay in the infants' department about 15,000 days and in the educational department about 7500 days. It is also expected that many deserted mothers will be able to get employment as nurses after attending the schools and that deserted children will be taken care of. Naturally the effect of the institute will soon be felt all over the empire, if every year only a few hundred mothers and midwives profit by its teachings.

Dec. 26th, 1910.

## CANADA.

(FROM OUR OWN CORRESPONDENT.)

*Cocaine in Montreal.*

IN one police district alone in Montreal there are said to be over 600 young people of both sexes addicted to cocaine. So widespread has the habit become that judges have made several pronouncements upon the danger to the public, one asserting that "Cocaine is the worst danger to our social life in Montreal." The Dominion parole officer states that 12 per cent. of the prisoners ascribe their downfall to cocaine. From Sept. 10th to Nov. 20th the police records

show that 75 people have been arrested for selling the drug. 150 arrests and convictions have been made in the Recorder's Court since last May. Recorder Weir tells of the stream of mothers visiting him and imploring the authorities to save their children. The vice is most prevalent amongst young people between the ages of 16 and 24. In the very heart of the city there is said to exist a Cocaine Club, where children even may get the seductive drug. The Federal authorities are being appealed to to amend the criminal code with regard to cocaine.

*Ontario Medical Council's Wide Powers of Discipline.*

In December, 1909, an Ontario practitioner was charged with using an instrument on an unmarried woman for an unlawful purpose. He was acquitted by the courts. The College of Physicians and Surgeons of Ontario instituted an inquiry into his conduct under that section of the Ontario Medical Act which renders a practitioner liable to have his name erased from the Register if guilty of any infamous or disgraceful conduct in a professional respect. The practitioner objected to the College making this inquiry after having been acquitted in the courts of law of the country, and therefore sought an order from the courts prohibiting the College of Physicians and Surgeons from investigating charges against him. The action for the injunction came before Mr. Justice Riddell of the Ontario bench, who refused the motion of the practitioner in question. The main objection to the College conducting an investigation was that the acts charged were crimes, and that the College could not inquire into a crime. Interpreting the Act, Mr. Justice Riddell states that the causes for removal from the Register of the College are divided into two classes—(1) Crimes which in Canada are felonies or misdemeanours; and (2) infamous or disgraceful conduct in a professional respect. In the former cases these are left to the criminal courts; if convicted the name is to be removed for such cause. Over the second class the criminal courts have no jurisdiction, and therefore the College must itself make inquiry. Mr. Justice Riddell says: "The purport of the Act is, that if a medical man has been publicly tried in a court of criminal jurisdiction and has been there convicted of an indictable offence against the people he no longer has any right to be a registered practitioner. If he has not been so convicted the College must inquire into the facts of an alleged misconduct, and if misconduct is proved, whether such misconduct be a crime or not, so long as it is infamous or disgraceful in a professional respect, it is quite the same as if the medical man has been convicted of a crime." If the finding of the College is not to the liking of the medical man he may appeal to the Divisional Court, appears to be Mr. Justice Riddell's summing up of the situation, one which certainly puts a heavy onus on the accused.

*The Medical Witness and the Expert Witness.*

The same judge addressed the Academy of Medicine, Toronto, recently on the above subjects. As a preface to his remarks the learned judge quoted the ancient joke as to the comparative degrees of liars, and said that the extraordinary antics of some men when called as medical experts were a disgrace to the medical profession. In the main the medical witnesses were honest. If the medical witness gave evidence contrary to the fact or contrary to his real opinion, he was a criminal equal with the man who plunders bank vaults by means of dynamite. The most striking or shocking examples were in cases where insanity was set up as a plea. Too much stress, however, should not be laid on difference of opinion *per se*, for opinion might be the result of honest thought and conviction. In law, too, there was the same divergence, and expert witnesses should not be expected always and necessarily to agree upon matters of opinion, whether in medicine or otherwise. After giving some sound advice for the guidance of the medical witness, he dealt with the expert witness, and thought there was grave danger of the medical profession being discredited by the competition for expert witnesses in damage suits and criminal cases, as many seemed to become advocates for one side or the other. He thought it would be quite possible to have a physician, or a board of physicians, of high standing appointed by the Crown, or retained as Crown counsel are retained in criminal cases. The evidence of such experts would be available alike for prosecution and defence. In certain criminal cases it is now the practice in Ontario to appoint two experienced alienists in the employ of the Ontario Government, whose whole duty it is to determine the exact facts and who are at the disposal of the defence as well as of the prosecution. The whole question is one which has been a puzzling problem to physicians, lawyers, and jurists alike. The suggestion has been made that here in Ontario the Ontario Medical Association and the Ontario Bar Association should join forces towards having an expert testimony law placed on the statute books of the province.

*Dominion Registration.*

Dr. T. G. Roddick of Montreal has been successful in getting the medical councils of all the provinces in Canada to agree to the proposed amendment of the Canada Medical Act, 1902. This amendment has been introduced into the Canadian Parliament, now in session, by Dr. Black, member for Hants, Nova Scotia. If agreed to by the Federal Houses it will then have to be ratified by the local legislatures of each province. As all the provinces, so far as the profession is concerned, have assented to the amendment, there is now every likelihood of Dominion Registration becoming the law of Canada. Then reciprocity will be secured with the General Medical Council of Great Britain.

Dec. 24th, 1910.

## UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

*Report of an International Commission on the Control of Bovine Tuberculosis.*

AN International Commission, formed under the auspices of the American Veterinary Association and consisting of members of the medical profession, veterinarians, and some laymen of the United States and Canada, in a recent exhaustive report recommended that legislation regarding the control and eradication of tuberculosis among domestic animals be rendered uniform; that the laws of the United States and Canada and other American countries for the admission into America of animals from without be made stringent and as much alike as possible; and that the laws governing the inter-state and inter-provincial movement of cattle and that between different American countries be harmonised. In concluding its report the Commission suggests that provision should be made to carry on the work, either by continuing the Commission as at present constituted, or with such changes in the *personnel* as may be considered desirable.

*Employer's Liability in the United States.*

It has long been known that the United States is much behind European countries in laws safeguarding workmen from injury and guaranteeing to them compensation for loss of wages through disability from injury, or to their families in case of fatal accident. That ingenious appliances are not lacking is proved by the fact that the American Museum of Safety has recently opened in New York City a permanent exhibition of various machines and models which demonstrate simple, practicable safeguards adapted to the needs of the American employer for protecting the lives and limbs of his workmen. It is hoped that this exhibition, by showing that at least 50 per cent. of the present appalling number of accidents are preventable, will lead to proper legislation in the various States, whereby the employer shall be rendered criminally liable for not providing his factory with safeguarding appliances, as well as be forced to provide some system of insurance for the families of killed or injured labourers.

*A Society of Medical Sociology.*

A new medical society has applied for incorporation in the State of New York, and formulates its somewhat novel purposes as follows:—

Recognising the intimate relationship between disease and the social-economic system under which we live, recognising that many diseases are caused directly by our social and economic conditions, recognising that the efficiency or inefficiency of our treatment often depends upon the economic conditions of the patient, recognising that there are many problems deeply and vitally affecting the welfare of mankind which are left practically untouched by any existing medical society, the American Society of Medical Sociology has been organised for the purpose of studying radically all questions of a socio-medical nature, and invites your cöoperation.

*Organised Relief and Distress in New York.*

The Charity Organisation of the City of New York in its annual report on Dec. 10th, 1910, says that the number of families cared for in the period covered by the report was 7616, as compared with 8172 in the previous period. The

relief disbursed amounted to $79,222, as against $84,625. Altogether the society disbursed for general work $132,377, a decrease of 7 per cent. There was an increase in the deficit in the funds for this work, however, of 22 per cent. The society considers it doubtful if the low figures of relief work in the years preceding the financial disturbance will ever be reached again because of the fact that the society is reaching persons who in former years would not come for help from organised charity. The amount of distress has been seriously increased by the general rise in the cost of all articles of food and clothing without any corresponding rise in wages. The organisation has been obliged to cut down its supplies of meat to each deserving family to twice weekly, to eliminate fresh vegetables, to reduce milk and butter to the lowest possible amounts, and it has well-nigh reached an irreducible minimum of tea and coffee. The effects of these reductions are already plainly apparent in the poorer physique of adult applicants for relief and in the stunted look of the children.

*Public Exhibitions of Bacteriology.*

The American Museum of Natural History is about to open a very completely equipped bacteriological laboratory. Physicians who desire certain specimens are at present obliged to send as far as Prague for them, unless some private laboratory happens to have what they want. This new laboratory will act as a base of supplies for similar laboratories all over the country. A series of public exhibitions is being arranged. These, together with public lectures on bacteriology under the auspices of the public school system, will, it is hoped, eventually have an excellent effect on the public attitude towards the medical profession, and demonstrate to the public the actual scientific basis of modern medicine.

*Traffic in Rotten Eggs.*

The New York Health Department has just inaugurated a crusade against the "rots and spots," as the eggs are called purchased by the cheaper class of bakers and confectioners. Whereas eatable eggs sell for about 2*s.* a dozen in the depth of winter, 1 pound of a mixture of rotten yelks and whites, or the contents of about 12 eggs, can be obtained by a baker for 1½*d.* This nefarious trade is hard to detect, for the cakes and bread made from bad eggs present a very good appearance.

*Cholera.*

Fear of the cholera has led to exceptionally careful examination of all incoming ships. On a ship arriving from Naples on Nov. 17th nine persons were found to be ill of cholera, and there had been two deaths from the disease during the voyage. News came recently from Quebec, Canada, that a case of cholera had been discovered on the steamer *Royal George*. Subsequent investigation proved the case to be merely one of gastro-enteritis, but the officers of the ship in question are in trouble for failing to report it, and the owners are liable to a heavy fine.

*Windfalls for Institutions.*

Munificent gifts of land and money have been made recently to the Tuberculosis Preventorium at Lakewood, N.J., which will soon be able to take care of over 200 children simultaneously on some 300 acres of ground. The New York Hospital for the Ruptured and Crippled also has benefited by the remarkable rise in real estate prices in New York. It has sold its property, mainly to a railway, for £270,000, probably five times what was paid for it many years ago.

*Forged Licences to Practise.*

Discovery has been made of a large number of forged certificates to practise medicine and dentistry in New York, and investigation as to the holders of such forgeries will be difficult and probably incomplete.

Dec. 23rd, 1910.

## NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

*Public Health Matters.*

AN influential deputation, consisting of the members of the standing committee of the South African Medical Congress, and practically all of the medical Members of Parliament, has recently waited by appointment on the Right Hon. the Prime Minister, General Botha, and the Hon. the Minister for the Interior, General Smuts, and communicated to them the unanimous wish of the medical profession in South Africa, as expressed in the resolutions passed at the last meeting of Congress, to the effect that, *inter alia*, a Portfolio of Public Health should be created, to be held, if need be, in combination with some other portfolio, and that a medical officer of health for South Africa should be appointed and should be the sole administrative head of the new department. The views of the profession were admirably voiced by Dr. Mathew Hewat, health officer for the Mowbray municipality. To Dr. C. F. K. Murray, the President of the Congress, were entrusted the resolutions regarding the proposed General Medical Council for South Africa, and he also ably fulfilled his task. At the conclusion General Smuts stated that the matters brought forward were of serious moment, and that the resolutions would be taken into consideration by the Government. Since the interview, however, nothing has been done by the Government in the direction desired, and it is regarded as fairly certain that the resolutions will be pigeon-holed unless the profession continues the agitation. It is felt that before Ministers can be expected to realise the gravity of continuing present methods of administration of public health affairs, and before Parliament can be expected on non-party lines to bring pressure to bear on the Government, the public at large will have to be educated, and the local organising committee now proposes, before taking further steps, that members of the profession should throughout the country attempt by letters to the lay press to show the really urgent need for a State Department of Health. It is thought that the facts regarding existing methods of administration have only to be clearly put before the public when the need for such a department will be realised and its creation undertaken in deference to public opinion. But the local organising committee is desirous above all that the question should not be regarded as a party one. Meanwhile there are grave matters intimately affecting the health of the people within the Union, which, without a proper department under the control of a chief administrative medical officer, can at present but inadequately be dealt with. To mention but a few of these. There is the guarding of the State against the introduction of infectious diseases from beyond its boundaries at the ports and in the north. We know to our cost the need for an efficient and coördinated port health service in South Africa. We have had experience of plague on several occasions introduced from India and elsewhere. This disease is only too likely to be introduced again at any time by sea, and when introduced it will be, as before, exceedingly difficult to eradicate owing to the extreme rat infestation of our ports and many of our inland towns. Apart from the necessity of taking adequate precautions against the introduction of plague by rodents in vessels arriving from India and other infected countries (even England), there are at present epidemics of cholera in Russia, Asia, and Madeira, and if cholera were introduced at this time into South Africa it might be difficult to combat. Beyond the boundaries of the Union in the north there is sleeping sickness, apparently slowly but surely finding its way south. Within the Union there are problems already urgently demanding attention, such as malaria, leprosy, syphilis, tuberculosis, and small-pox, as well as the question of State supervision of the mines. In portions of the Transvaal malaria prevents whole districts from becoming properly developed. A large number of lepers are segregated within the Union, but there are probably over 2000 still at large. Many of these have been reported to the authorities, but owing to lack of accommodation in the leper settlements have not been removed from their homes. Syphilis is rampant and practically uncontrolled in certain native areas, particularly in portions of the Transvaal, in Bechuanaland, and in parts of Zululand. In Bechuanaland it is stated that actually nearly 4 per cent. of the native population is being treated for this disease, but the administrative arrangements are defective, and a large number of infected persons receive no treatment. In the Transvaal the arrangements are even more unsatisfactory, while in Zululand practically nothing is being done by the Government at all. Tuberculosis is prevalent all over South Africa and is becoming year by year more and more serious, particularly amongst the native races. Its spread has been due to defective housing, particularly in the towns, but much more to the unsatisfactory conditions under which natives work and live at the mines. All these matters and many others demand the attention of an active department. They would, however, appear to be

receiving but scanty attention at present, though eventually the country will have to pay, and pay heavily at that, for neglecting the safeguarding of the health of its citizens. As far as the Transvaal is concerned, there has been no efficient health service since Dr. George A. Turner, the medical officer of health under Crown Colony Government, was retrenched, which took place soon after the advent of responsible government in that colony. In the Orange Free State and Natal small but defective health administrations existed prior to Union and have been practically left untouched since Union. In Cape Colony, a strong State department existed until the accomplishment of Union, when it was broken up. It is not too late for this to be reconstructed, and after amalgamation with the other health administrations it might serve South Africa with the success with which it formerly served the inhabitants of Cape Colony. It is the object of the profession in South Africa to see that public opinion is aroused to insist upon reform before it is too late.

*Death of Dr. John Greathead.*

On Oct. 26th, in an almost inaccessible portion of British East Africa, a well-known and greatly respected practitioner in South Africa, Dr. John Greathead, met his death from pneumonia and, so it is stated, sleeping sickness while on a shooting expedition. Dr. Greathead had for many years a large practice at Grahamstown in Cape Colony, and was virtually the only surgeon with any considerable consulting practice in the Eastern Province. He was a brilliant surgeon, with a considerable experience and ability in ophthalmic work. He is perhaps best known to South Africans as a member of the Medical Council of Cape Colony. By his death the profession has suffered severe loss.

*Medical Education.*

During the past two years there has been a movement to cheapen the cost of medical education to South African students who hitherto have had to take out the whole five years' curriculum at a recognised medical school in the British Isles. Last year, however, the passing of the examination in botany, chemistry, physics, and biology was recognised by the authorities of the Edinburgh University as exempting students from the corresponding examination at the latter institution, and the course of study for such examination was in consequence permitted to count as one year in the student's curriculum. Edinburgh has always attracted medical students from South Africa far more than any other educational centre in the old country, and the reason is obvious, for it has always afforded all possible facilities to colonial students. The recognition of the preliminary science examination, as above mentioned, has increased the tendency of students from this country to select the Edinburgh University as their Alma Mater, and it is expected that the other examining bodies and universities, unless debarred by their Charters or Acts of Incorporation, will follow suit, as, indeed, the Royal Colleges in England have already recently done. An arrangement was entered into a few months ago between the South African College (one of the oldest and best endowed colleges affiliated to the Cape University) and certain examining bodies in Great Britain, whereby a proposed course of tuition at the College has been approved of as satisfying the requirements in respect of laboratory instruction for the D.P.H. examinations. The medical officer of health of the City of Cape Town has been appointed honorary lecturer on hygiene to the College, and it is understood that he is expected to give all the laboratory instruction required, at any rate in bacteriology. Proper tuition in chemistry for the purpose of the course is already obtainable at the College and should be given by the professor of chemistry, if this has not already actually been arranged. It is not felt, however, by the profession generally that sufficient instruction in bacteriology can be given except by a specialist in bacteriology, and it is probably this feeling which has hitherto kept intending candidates from taking out the course locally. Under all the circumstances it would not seem amiss if the General Medical Council looked into the matter. Within the last few months another step forward in educational policy has been decided upon by the same College and one which will meet with universal approval—namely, the establishment of chairs of anatomy and physiology. The late Government of Cape Colony was interested in the matter and promised financial support. This promise has been ratified by the Government of the Union, which has placed on the Estimates for consideration by Parliament sums of money in aid of the necessary buildings and provision for the salaries of professors of anatomy and physiology respectively. It is expected that these will be sanctioned by Parliament without difficulty, subject to the condition that if a national teaching university should ever be established the college authorities will not oppose the transfer of such chairs to the university. Plans for the new buildings are now being considered by the college council, and it is expected that building operations will be put in hand at an early date. An Anatomy Act has, I understand, been prepared and will be submitted to Parliament some time this session. It is stated to be framed on the lines largely of other colonial statutes, particularly the State Ordinances of Australia and Canada. It provides, *inter alia*, for the licensing of schools of anatomy and for the appointment of inspectors of anatomy. Also that the body of any person dying in a public hospital, asylum, or penal establishment which is not claimed within 24 hours may be handed over to an inspector of anatomy for the purpose of being prepared for dissection, and if not claimed within a fortnight thereafter may be used at any licensed school for the purposes of dissection. It is not thought that the proposed Act will meet with any opposition, and it will doubtless shortly receive the sanction of Parliament. When these chairs have been established the college will have to obtain recognition of the course of tuition, so as to enable students to proceed home for the purpose of entering for the second professional examination without having to take out courses of instruction in these subjects there, and then it should be possible for a South African student to qualify in medicine after three years' residence at such educational centre out of South Africa as he may select. It will be some years before any further step forward in the direction of providing medical education locally will be possible. If this scheme is energetically carried through it should secure for Cape Town the South African Medical School of the future. Cape Town can no longer be the centre of administration, but it is likely that, besides being the legislative capital of the Union under the constitution, it will become the most important educational centre in South Africa, for which it must be admitted it is admirably fitted on account of its climate and magnificent surroundings, although many would prefer to see such a centre established in the north.

Dec. 4th, 1910.

# Obituary.

## JAMES EDWARD POLLOCK, M.D. ABERD., F.R.C.P. LOND., L.R.C.S. IREL.,

CONSULTING PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

IN the death of Dr. James Edward Pollock on Dec. 18th medicine has lost another of its distinguished veterans. Born in 1819 he was the son of a barrister, Mr. Edward Pollock, and after pursuing his medical studies in Dublin received his first diploma in 1840 as an L.R.C.S. Irel. In 1842 he began practice in Rome, but a few years later he received the degree of M.D. from King's College, Aberdeen. Coming to London, Dr. Pollock established himself in practice, his first appointment being that of physician to the Western General Dispensary. He was later elected physician to the Brompton Hospital for Diseases of the Chest, with which institution some of his best work is connected, and he held the office of consulting physician thereto at the time of his death.

His work at Brompton was most painstaking and accurate, and he served that institution faithfully, not only in a strictly medical capacity, but also on the committee of management, in which his wide knowledge of affairs proved very valuable in harmonising the sometimes divergent views of the economic and scientific aspects of benevolent institutions. In 1865 he published a work on the "Elements of Prognosis in Consumption," founded on an analysis of about 3500 undoubted cases of the disease. In these days of exact laboratory data upon which to found a correct medical judgment in regard to diagnosis and prognosis, it is remarkable, on looking through Dr. Pollock's book as it was first published, to observe how closely he forestalled, on clinical grounds alone, indications now substantiated and explained

by our modern knowledge of the pathology of pulmonary tuberculosis. As was said by us of the book at the time of its publication, it was "not manufactured from the writings of his predecessors," but was "the result of much honest and painstaking work on his own part." It may even now be consulted with advantage by those well enough versed in modern pathology rightly to interpret its deductions. In 1864 Dr. Pollock was elected to the Fellowship of the Royal College of Physicians of London, of which body he became a Censor in 1884. In 1893 he was Senior Censor, and in the same year, in consequence of the death of Sir Andrew Clark, acted as pro-President for the interregnum until the following presidential election. He was also a member of the Council and examiner in medicine. In 1883 he delivered the Croonian lectures on Modern Theories and Treatment of Phthisis, and in 1889 the Harveian oration.

In 1881 he was president of the Harveian Society and delivered the lectures on the Prognosis of Heart Disease. He was also a former vice-president of the Royal Medical and Chirurgical and Pathological Societies. He took great interest in the subject of life insurance, was medical officer of three societies, and was among the founders of the Life Assurance Medical Officers' Association, of which he was rightly chosen first president. Here, as in other fields, his careful observations, his accurate records, and his clear judgments were of the highest value, and his ripe experience was crystallised in the publication, in 1889, in conjunction with Mr. James Chisholm, an actuary already well known through his writings on the assessment of extra risks, of the "Medical Handbook of Life Assurance," a book the completeness, brevity, and trustworthiness of which were generally recognised. His other writings were chiefly lectures and contributions to the medical press on the subject of consumption. During the later years of his life he had an extensive consulting practice, and in 1895 was appointed physician extraordinary to Her Majesty Queen Victoria.

There were present at his funeral, which took place in Highgate Cemetery on Dec. 22nd, 1910, besides his relatives and friends, the President, the Senior Censor, and the emeritus and present registrars of the Royal College of Physicians of London, and, as representing the Brompton Consumption Hospital, Dr. Theodore Williams, Dr. R. Maguire, Dr. S. H. Habershon, Dr. H Batty Shaw, Mr. R. J. Godlee, and the secretary, Mr. Francis Wood. Dr. Pollock was a kindly genial gentleman, a courteous and learned physician with a dignified presence, and a worthy representative of the best traditions of medicine. After a full life of active work, crowned with the leisure earned thereby, he died at a ripe age, holding the esteem and affection of his colleagues and of a wide circle of friends.

Dr. Theodore Williams writes:—"The Brompton Hospital and the College of Physicians have lost one of their most striking personalities by the death of Dr. J. E. Pollock at the advanced age of 92. From the year 1867, when I joined the staff of the Brompton Hospital as assistant physician, until shortly before his death, I was on very intimate terms with Dr. Pollock, and as a friend and colleague I profited by his sagacious and wise counsel and by his sterling example. As a clinical and scientific physician he was quite a model. His methods of auscultation and percussion, derived, I believe, from the late Dr. Stokes of Dublin, were most accurate and were carried out with the greatest precision. Then came the diagnosis, and, perhaps the most valuable of all, on which this was based, were the succinct notes to be found on Dr. Pollock's ward cards. The worth of his notes can be realised from the fact that his well known work on the 'Elements of Prognosis in Consumption' dealt with 3500 cases, and all these were noted by his own hand. Dr. Pollock held strongly to the large part played by the constitutional powers, the soil as it is termed, in distinction to the seed or tubercle bacillus, in the evolution of phthisis, and always dwelt on the importance of strengthening these powers in every possible way. He was one of the earliest advocates of the open-air treatment of the disease. He laid great stress also on heredity, and was the first in England to point out the large proportion of acute cases in which heredity was present and also how rare hæmoptysis was in these cases. Dr. Pollock's statistics were some of the early factors of the more favourable view of consumption that is now held, and he applied these statistics to life assurance, obtaining many interesting figures and results. He was one of the best examiners for life insurance I have ever known, and he owed this principally to his large experience, both in life offices and in hospital and private practice. With regard to Dr. Pollock's conduct as a colleague on the administration of the Brompton Hospital, I cannot give too much praise. To his colleagues he was most loyal, always considerate and deferential to seniors and even to those of his own standing, and encouraging and stimulating to juniors, often affording them opportunities for work and distinction by placing his wards at their disposal and infusing us all with a high standard of professional duty and honour. Perhaps where he shone most was in his relations with the Brompton Hospital committee of management, which for many years it was his duty, as chairman of the medical committee, to attend. Dr. Pollock had the happy knack of placing the latest appliances of modern medicine and surgery in so clear a light that the desirability of their adoption became at once obvious, and the committee after a time valued his opinion very highly. Naturally Dr. Pollock, while loyal and kind hearted, showed his Hibernian origin in loving a fight, and a right good fighter he was, as might be occasionally witnessed at the medical societies. He was an eloquent speaker and a clear writer. Dr. Pollock was an affectionate husband and a fond father, while truly his left hand did not know of the many self-sacrificing and generous acts of mercy which his right hand did, and which made his name a blessed one in many a poor family, by whom he was loved and respected as much as by his colleagues and his friends."

---

## WILLIAM BAIRD McQUITTY, M.A., M.D. R.U.I., D.P.H. CAMB.

IT is with sincere regret that we announce the tragically sudden death of one of the most brilliant of the younger physicians of the Belfast medical school, Dr. W. B. McQuitty, which occurred on Friday night, Dec. 30th, 1910, at his residence, University-square, Belfast, from cerebral hæmorrhage, after only half a day's illness, at the early age of 48. Dr. McQuitty was a native of Belfast, son of the late Mr. James McQuitty, a Belfast merchant. He was a foundation scholar at the Royal Academical Institution, Belfast, from which he entered Queen's College in 1881–82. There he had a most brilliant career, being both a junior and a senior scholar, and at the Royal University he took first-class honours at the B.A., M.A., and M.D. degree examinations, and also gained the studentship in experimental science. He subsequently studied at the Rotunda, Dublin, at the London Hospital, and at the Hospital for Sick Children, Great Ormond-street. He was a D.P.H. of Cambridge. Settling down in his native city, he was first attached to the Ulster Hospital for Children, but on Oct. 27th, 1900, his real life work began when he was appointed assistant physician to the Royal Victoria Hospital. There he used all his previous training to enable him to get a thorough practical acquaintance with disease, and not only did he by this experience become himself a physician, but he gathered round him session after session a large class of students, who appreciated to the utmost his thorough mastery of the diagnosis and treatment of the patients, and who subsequently, when they began practice, frequently called him in consultation. As a result, during the past five years Dr. McQuitty gradually became one of the most valued consulting physicians in the North of Ireland, an advancement due alike to his abilities and to his training in general and in hospital practice. He appeared at times to the greatest advantage at the local medical societies when, with the keenest powers of observation, he showed very rare cases, and at the same time indicated by a few words his complete knowledge of medical literature. Dr. McQuitty was a man of the most amiable and kindly disposition; he had brains, grit, levelheadedness, and the greatest power of work. He impressed all who came into contact with him as a physician who thoroughly examined each case in the most careful way, availing himself of every avenue of diagnosis A man who had no showy or evanescent qualities, he gave one the impression of great reserve power, and those who knew him best clearly saw that every year he improved in both skill and knowledge. His death, at such a comparatively early age, is a great loss to the public of the North of Ireland, to the profession, and to the Belfast Medical School. A true friend, a loyal colleague, and a most conscientious and able physician, his death is lamented by everyone in Belfast. Although Dr. McQuitty was unmarried, one of the saddest features connected with his early decease is the fact that he had quite recently

become engaged. He was buried in the city cemetery, Belfast, on Jan. 2nd, his remains being followed by a concourse of his professional brethren and of the public.

### WALTER BROCK DE JERSEY, M.B., B.C. CAMB., M.R.C.S. ENG., L.R.C.P. LOND.

THE death of Dr. Walter Brock de Jersey of Guildford, which occurred at Ascot last month at the early age of 47 years, has been learned with great regret by a large circle of patients and friends.

Dr. de Jersey was the son of Mr. Carey de Jersey of Guernsey. He was educated at Elizabeth College, Guernsey, and Marlborough. He proceeded to Pembroke College, Cambridge, in 1881, graduated B.A. in 1884, and entered at St. Thomas's Hospital in 1886. In 1889 he qualified as M.R.C.S Eng., L.R.C.P. Lond., and graduated M.B., B.C. Camb. in 1890. He held the posts of house physician and clinical assistant in the Ear Department at St. Thomas's Hospital, and subsequently that of house surgeon and senior resident medical officer at the Evelina Hospital for Sick Children. After a voyage to the West Indies with Lord Brassey on the *Sunbeam*, as medical officer, he married in 1893, and having engaged in private practice in London for a short time finally settled in Guildford in 1895. For several years past he had been honorary medical officer to the Royal Surrey County Hospital, where his loss is much deplored by his colleagues and the staff of that institution.

His health had been failing since the summer, but he continued with his work and only reluctantly gave up some three weeks before his death to go to a nursing home at Ascot. His untimely death came as a painful surprise to his friends and patients, as it was not generally known that he was seriously ill. He was buried at Stoughton Cemetery, Guildford, the first part of the service taking place at Christ Church, which was attended by a large and representative gathering, including all the medical men in practice in the town and many former patients. He leaves a widow, a son, and two daughters to deplore the loss of a much-loved husband and father.

A friend and neighbour writes to us as follows:—"Dr. de Jersey was ever ready to assist his colleagues, and the writer had frequent opportunities of appreciating the kindliness and generosity of his nature. He adopted a high standard of professional etiquette, and his advice on this and other matters was readily given and greatly valued. He was much attached to his work and took a personal interest in all his patients. I am able to quote the following expressions of the esteem and confidence which he inspired in his patients. 'Dr. de Jersey,' writes one patient, 'had characteristics and qualifications which make his loss seem irreparable to those of us who esteemed it a privilege to consult him as the "family doctor." The entire absence of the spirit of the "high priest," a wonderful sympathy, and the perfect courtesy of the best type of an English gentleman united in confirming the confidence which his professional skill inspired.' Another writes: 'Rich in saving common sense, and possessed of a ripe and well-balanced judgment, his advice on matters non-medical was frequently sought with the happiest results.'"

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Wilhelm Jaeger of Darmstadt, for many years surgeon to the Municipal Hospital and previously assistant to Professor Gustav Simon at Heidelberg. His age was 72 years.—Dr. Ludwig Toinwaldt, a well-known laryngologist of Dantzig, aged 67 years.—Dr. Samuel Alexander, professor of genito-urinary diseases in Cornell University Medical College, New York.—Dr. Ch. A. Herter, professor of materia medica and therapeutics in the New York College of Physicians and Surgeons.—Dr. F. Fée, inspecting medical officer of the French Army Medical Service.—Dr. G. Profeta, professor of dermatology in the Genoa Medical School.—Dr. Johann Fritsch, extraordinary professor of mental diseases in Vienna.—Dr. Wilhelm Fischel, *privat-docent* of midwifery and gynæcology in the German University of Prague.

A SOMERSET CENTENARIAN.—Mrs. Elizabeth Andrews died at Street, Somerset, last week in her 102nd year.

# Medical News.

UNIVERSITY OF LONDON.—At examinations held in December the following candidates were successful:—

M.D. EXAMINATION.

*Branch I., Medicine.*—Charles J. Armstrong-Dash, B.S., St. Bartholomew's Hospital; Henry Swarbrick Brown, Guy's Hospital; John Hay Burgess, St. Mary's Hospital; Cecil Clarke, B.S., University of Bristol and University College Hospital; Herbert Rees Davies, B.S., London Hospital; Edward Vincent Dunkley, B.S., St. Thomas's Hospital; Dan Arthur Powell, B.S., Charing Cross Hospital; William Hebert Smailes, B.S., University of Leeds; William Rees Thomas, B.S., University College, Cardiff, and Charing Cross Hospital; and Rawdon Augustus Veale, B.S., University of Leeds.

*Branch II., Pathology.*—Edgar Hartley Kettle, B.S., St. Mary's Hospital.

*Branch III., Mental Diseases and Psychology.*—John George Porter Phillips, B.S., University College and Guy's Hospitals.

*Branch IV., Midwifery and Diseases of Women.*—Mary Alice Blair, B.S., London (Royal Free Hospital) School of Medicine for Women; Herbert Orpe Brookhouse, B.S., Guy's Hospital; Ethel Constance Cousins, B.S., London (Royal Free Hospital) School of Medicine for Women; Herbert Bowly Gibbins, St. Bartholomew's Hospital; William Gilliatt, B.S. (University Medal), Middlesex Hospital; Anna Maude Seaton Smith, London (Royal Free Hospital) School of Medicine for Women; Thomas G. Starkey Smith, B.S., St. Thomas's Hospital; and Bessie Weldon Symington, B.S., Ruth Helen Western, B.S., and Sophia Margaret V. Witts, B.S., London (Royal Free Hospital) School of Medicine for Women.

*Branch V., State Medicine.*—Lilian Ethel Wilson, B.S., London (Royal Free Hospital) School of Medicine for Women.

*Branch VI., Tropical Medicine.*—Leonard Gilbert, B.S., St. Thomas's Hospital; Henry Crewe Keates, B.S., Guy's Hospital; John Preston Maxwell, B.S., St. Bartholomew's Hospital and London School of Tropical Medicine.

M.S. EXAMINATION.

*Pass-list.*—Frederick James Fitzmaurice Barrington, University College Hospital; Harry Blakeway, B.Sc., St. Bartholomew's Hospital; Edward Musgrave Woodman (University Medal), St. Bartholomew's Hospital.

FIRST EXAMINATION FOR MEDICAL DEGREES.

*Pass-list*—Reginald George Abrahams, University of Birmingham; Frank Macdonald Allchin, King's and Birkbeck Colleges; Kevin Doyle Atteridge, St. Bartholomew's Hospital; Christopher Percival Barber, Charing Cross Hospital; Kanshi Ram Betra, University College; Claude Wells W. Baxter, Plymouth Technical Schools; Eric Biddle, University College, Cardiff, and Guy's Hospital; Frank Chadwick, Victoria University of Manchester; Dorothy Chick, London (Royal Free Hospital) School of Medicine for Women; Llywelyn ap Ivan Davies, University College; Eric Gordon Dingley, St. Bartholomew's Hospital; John Ralph Dingley, University College; Geoffrey Barrow Dowling, Dulwich College and Guy's Hospital; *Langdon Percival L. Edwards, Whitgift Grammar School; Robert Hood Fleming, B.Sc., Middlesex Hospital; Ronald Kelson Ford, London Hospital; Annie Mary Forster, London (Royal Free Hospital) School of Medicine for Women; Gerald Francis Petvin Gibbons, Epsom College and St. Bartholomew's Hospital; Olaf Gleeson, private study; George Edwin Heath, Derby Technical College; †Geoffrey Oliver Hempson, University College; Dorothy Muriel Henty, London (Royal Free Hospital) School of Medicine for Women; Ernest Eugène Herga, London Hospital; Hugh Llewelyn Glyn Hughes, Epsom College and University College; John Powell Jones Jenkins and Rhys Bevan John, University College, Cardiff; Louis Gaston Le Blanc, St. Bartholomew's Hospital; Adeline Mabel Matland, London (Royal Free Hospital) School of Medicine for Women; Allan Hawkins Morley, London Hospital; Hugh Roger Partridge, University of Leeds; Leonard George Phillips, Middlesex Hospital; Emma Christine Pillman, London (Royal Free Hospital) School of Medicine for Women; William Kenneth A. Richards, University of Bristol; Ralph Leslie Robinson, University College; Trevor Cecil Russell, St. Mary's Hospital; Lionel Frederick Strugnell, St. Bartholomew's Hospital; Rufus Clifford Thomas and William Henry Thomas, University College, Cardiff; *William Leslie Thomas, Swansea Technical College; and Henry Wardel Snarey Wright, University College.

* Awarded a mark of distinction in Physics.

† Awarded a mark of distinction in General Biology.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

LONDON SCHOOL OF TROPICAL MEDICINE.—The result of the examination at the thirty-fourth session of this school (October–December, 1910), showed that the following passed:—

K. B. Allan, M.B., B.S. Durh., Colonial Service; *W. M. Anderson, Captain, I.M.S., M.D., B.S. Lond.; H. G. Barrie, M.D., C.M.; *F.V.O. Beit, Captain, I.M.S., M.B.Lond.; L. H. Booth, M.R.C.S., L.R.C.P., Colonial Service; *R. St. John Brookes, M.B., B.Ch. Dub., D.P.H. Dub.; Miss N. G. Cotton, M.B., B.S. Lond.; *J. Donnelly, M.B. Irel., Colonial Service; *L. E. Gilbert, Captain, I.M.S., M.B, B.S. Lond.; Miss I. Kahn, M.D. Michigan; *H. C. Keates, Captain, I.M.S, M.B., B.S. Lond.; *C. A. Lane, Major, I.M.S., M.D. Lond.; *J. H. Murray, Captain, I.M.S., M.B, M.R.C.S., L.R.C.P., D.P.H.; G. Rollason, L.M.S.S.A., Colonial Service; R. S. Roper, F.R.C.S. Edin., M.R.C.S., L.R.C.P.; W. A. Ryan, L.R.C.P., L.R.C.S. Irel., Colonial Service; A. J. Smith, M.B. Birm., Colonial Service; C. S. Thompson, M.B., B.S. Durh., Colonial Service; J. F. W. Ward, L.R.C.P. & S. Edin., Colonial Service; *W. G. Watt, M.B., Ch.B. Aberd., Colonial Service; *H. G. Stiles Webb, Captain, I.M.S., L.R.C.P., M.R.C.S., D.P.H.; and F. T. Wills, M.B., C.M. Edin.

* Passed with distinction.

UNIVERSITY OF CAMBRIDGE.—At examinations for Medical and Surgical degrees, held in Michaelmas term, 1910, the following candidates were successful:—

FIRST EXAMINATION (*October, 1910*).

*Part I., Chemistry*.—K. H. Ashby, Emmanuel; A. O. Courtis, Pembroke; E. Forrester-Paton, King's; H. K. Graham-Hodgson, Clare; W. Hillbrook, Emmanuel; P. D. Pank, Caius; S. R. Prall, Emmanuel; H. E. Rhodes, King's; T. Schäfer and J. G. T. Thomas, Caius; F. H. Vey, B.A., Clare; and F. H. Young, Trinity.

*Part II., Physics*.—K. H. Ashby, Emmanuel; F. M. Davis, Caius; E. Forrester-Paton, King's; H. K. Graham-Hodgson, Clare; E. H. V. Hensley, King's; W. Lambert, Corpus Christi; H. W. Leatham, Trinity; F. G. Lewtas, Caius; C. R. Mackenzie, Trinity; T. D. Morgan, Jesus; P. D. Pank, Caius; S. R. Prall, Emmanuel; H. E. Rhodes, King's; T. Schäfer, Caius; F. H. Vey, B.A., Clare; and F. H. Young, Trinity.

*Part III., Elementary Biology*.—J. G. Davies, Emmanuel; F. M. Davis, Caius; E. Forrester-Paton, King's; W. Hillbrook, Emmanuel; C. E. Kindersley, Magdalene; H. W. Leatham, Trinity; T. D. Morgan, Jesus; S. R. Prall, Emmanuel; and T. Schäfer, Caius.

FIRST EXAMINATION (*December, 1910*).

*Part I., Chemistry*.—G. F. V. Anson, Trinity; J. V. Bates, Pembroke; J. T. Bleasdell, H. Selwyn; E. L. Caldwell-Smith and H. Chadwick, Trinity; J. G. Davies, Emmanuel; J. R. Earp, St. John's; J. D. Gabb, Caius; S. G. Galstaun, Trinity; C. Gardiner-Hill and E. O. Goldsmith, Pembroke; J. R. Harris, Queens'; E. H. V. Hensley, King's; L. W. Jones, Emmanuel; H. W. Leatham, Trinity; T. R. M. Livesey, King's; F. McCormick, Magdalene; G. L. Mau'e, Christ's; E. O. Morrison, Caius; P. R. O'R. Phillips, Pembroke; R. L. M. Wallis, B.A., Downing; and Franklin G. Wood, Jesus.

*Part II., Physics*.—G. F. V. Anson, Trinity; J. V. Bates, Pembroke; R. C. Bentley, Queens'; J. T. Bleasdell, H. Selwyn; E. L. Caldwell-Smith and H. Chadwick, Trinity; H. Chell, St. John's; E. H. Dendy, Caius; J. R. Earp, St. John's; J. S. Ellis, Trinity; H. J. Ewart, King's; S. G. Galstaun, Trinity; C. Gardiner-Hill, Pembroke; J. R. Harris, Queens'; W. Hillbrook and L. W. Jones, Emmanuel; M. E. MacGregor, Trinity; E. O. Morrison, Caius; P. R. O'R. Phillips, Pembroke; R. M. Savur, non-collegiate; J. A. D. Skinner and J. G. T. Thomas, Caius; R. L. M. Wallis, B.A., Downing; A. G. P. Wills, Corpus Christi; and Franklin G. Wood, Jesus.

*Part III., Elementary Biology*.—J. V. Bates, Pembroke; J. J. O. Beven, Christ's; E. L. Caldwell-Smith, Trinity; H. K. Graham-Hodgson, Clare; F. G. Lewtas, Caius; T. R. M. Livesey, King's; C. R. Mackenzie, Trinity; H. E. Rhodes, King's; R. M. Savur, non-collegiate; F. H. Vey, B.A., Clare; R. L. M. Wallis, Downing; and U. G. Williams, Caius.

SECOND EXAMINATION (*October, 1910*).

*Part II., Pharmacology and Pathology*.—K. B. Aikman, B.A., Clare; D. C. G. Ballingall, B.A., Emmanuel; R. St. L. Brockman, B.A., Caius; E. N. Butler, B.A., Clare; G. d'R. Carr and G. M. Chapman, Caius, J. Deighton, B.A., Trinity; G. D. East, B.A., Emmanuel; A. T. Edwards, St. John's; H. H. M. Gould, Clare; J. L. Green, B.A., Downing; A. N. Hooper, B.A., Emmanuel; G. D. Jameson, B.A., Pembroke; A. R. Jennings, B.A., Jesus; A. R. MacMullen, B.A., Caius; H. Y. Mansfield, B.A., Emmanuel; F. D. Marsh, B.A., Trinity; E. G. Martin, Trinity Hall; J. A. Martin, B.A., and V. C. Pennell, Pembroke; S. G. Platts, B.A., Caius; Ff. Roberts, B.A., Clare; D. N. Seth-Smith, B.A., Emmanuel; T. H. G. Shore, B.A., and A. V. Stocks, B.A., St. John's; P. Stocks, King's; W. J. F. Symons, B.A., Sidney Sussex; H. F. W. Warden, B.A., Pembroke; and E. Wordley, B.A., Emmanuel.

SECOND EXAMINATION (*December, 1910*).

*Human Anatomy and Physiology*.—E. D. Adrian, Trinity; C. S. Atkin, B.A., and L. W. Barlow, B.A., Caius; H. A. Bell, B.A., Jesus; P. H. Berry, B.A., King's; M. W. K. Bird, Emmanuel; P. R. Boswell, Queen's; E. J. Boyd, B.A., Sidney Sussex; E. C. Bradford, Pembroke; E. J. Bradley, Jesus; E. H. P. Brunton, B.A., Trinity; F. L. Cassidi, B.A., Corpus Christi; W. H. W. Cheyne, B.A., and B. K. T. Collins, B.A., Trinity; G. D. Compston, Trinity Hall; L. P. Costobadie, Caius; G. M. Cowper, Trinity; H. E. Creswell, B.A., Caius; H. L. Cronk, Jesus; J. Ll. Davies, Emmanuel; H. P. Dawson, B.A., and H. V. Deakin, B.A., Trinity; J. M. Evatt, Caius; G. C. Fairchild, B.A., Sidney Sussex; W. D. Galloway, B.A., Clare; C. L. Gimblett, Caius; W. B. Gordon, Clare; A. Griffith-Williams, Trinity; H. Hartridge, B.A., King's; A. D. Haydon, B.A., Caius; R. J. Hearn, Jesus; T. J. H. Hoskin and A. M. Humphry, Trinity; B. L. Hutchence, Caius; J. S. Kennedy, B.A., King's; S. D. Kilner, Emmanuel; G. C. King, B.A., Caius; C. L. Lambrinudi, B.A., Christ's; A. A. Lees, Emmanuel; W. M. Lupton, B.A., Clare; T. W. Maunsell, Caius; E. S. Mawe, King's; C. F. Mayne, B.A., Caius; R. K. Merson, Emmanuel; A. E. Panter, B.A., Clare; F. S. L. Piggott, Emmanuel; H. A. Richards, B.A., Clare; E. L. K. Sargent, B.A., St. John's; C. J. Scholtz, B.A., Emmanuel; J. E. Sharp, B.A., and L. W. Shalley, Caius; W. H. Shephard, Christ's; R. P. A. Starkie, Trinity; M. T. W. Steedman, B.A., Clare; C. R. A. Thacker, Downing; A. G. G. Thompson, Pembroke; E. W. Todd, Trinity; A. W. Uloth, Pembroke; D. C. L. Vey, Clare; P. Wallice, King's; C. A. Weller, B.A., Clare; F. A. Williamson, Queen's; and K. J. Yeo, B.A., Emmanuel.

THIRD EXAMINATION (*December, 1910*).

*Part I., Pharmacology and General Pathology*.—A. H. Birks, Caius; T. R. H. Blake, B.A., Pembroke; L. Bromley, B.A., and H. H. Brown, B.A., Caius; J. D. Clarke, B.A., Sidney Sussex; S. S. Crosse, B.A., Pembroke; J. P. H. Davies, B.A., Jesus; A. J. S. Fuller, B.A., Emmanuel; H. D. Gillies, B.A., Caius; P. Hamill, M.A., Trinity; E. C. Hardwicke, B.A., Corpus Christi; T. L. Hardy, B.A., H. Selwyn; J. P. Hill, M.A., Caius; W. H. Hodgson, B.A., and R. S. Kennedy, B.A., Christ's; G. A. Lilly, Caius; W. M. Oakden, B.A., Peterhouse; W. A. Peacock, B.A., Pembroke; E. G. T. Poynder, Clare; K. Pretty, B.A., King's; E. C. Rayner, B.A., Caius; J. F. Taylor, B.A., H. Selwyn; J. R. A. Todhunter, B.A., J. W. Tonks, B.A., R. J. Vernon, B.A., and C. B. Wainwright, B.A., Caius; H. K. Walker, Trinity; L. C. Walker, B.A., Christ's; and C. Warner, B.A., Pembroke.

*Part II., Surgery, Midwifery, and Medicine*.—The following have now satisfied the examiners in all three sections: H. W. Barber, B.A., Clare; H. G. Baynes, B.A., Trinity; C. C. H. Binns, B.A., Caius; A. S. Cane, B.A., King's; J. R. Dick, B.A., Downing; A. Feiling, B.A., Pembroke; R. Fisher, B.A., Sidney Sussex; A. J. S. Fuller, B.A., Emmanuel; H. D. Gillies, B.A., Caius; H. G. Greaves, B.A., Emmanuel; P. Hamill, M.A., Trinity; T. W. S. Hills, B.A., Downing; T. H. Just, B.A., Trinity; N. Mutch, B.A., Emmanuel; R. L. Rawlinson, B.A., Trinity; A. E. Rayner, B.A., Caius; H. B. Richmond, B.A., King's; J. B. Ronaldson, B.A., St. John's; F. D. Saner, B.A., Christ's; K. I. Singh, B.A., Pembroke; R. M. Soames, B.A., and C. J. Stocker, B.A., Trinity; R. M. R. Thursfield, B.A., H. Selwyn; W. W. C. Topley, B.A., St. John's; J. Van Schalkwijk, B.A., Caius; J. M. Weddell, B.A., Christ's; P. F. Wilson, B.A., Caius; and W. B. Wood, M.A., Jesus.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. B. Heymann of Breslau has been recognised as *privat docent* of Hygiene.—*Breslau:* Dr. R. F. Fuchs of Erlangen has been recognised as *privat-docent* of Physiology.—*Göttingen:* Dr. Albert Fromme has been recognised as *privat-docent* of Surgery.—*Gratz:* Dr. Alois Materna has been recognised as *privat-docent* of Pathological Anatomy.—*Heidelberg:* Dr. Ernst Kürz has been recognised as *privat-docent* of Forensic Medicine.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—At the prize distribution by the Right Hon. Lord Ilkeston on Dec. 15th last the subject of the relations between hospitals and their attached medical schools was the theme of several of the speeches. Sir John Wolfe-Barry did not think that the benefits of such an alliance were so much appreciated as they should be by the world at large, yet these advantages were both great and mutual. The recommendation of Sir Edward Fry's committee, that no money should be diverted from the individual relief of the sick poor for educational purposes, had prevented the governors of the hospital from coming to any great extent to the assistance of the school, but he looked to the help promised by the Board of Education. The Dean, Mr. E. Rock Carling, also referred to this subject in his report, saying that the conditions which had embarrassed the metropolitan medical schools of late years were still in operation, but they confidently expected some measure of relief from the labours of the Royal Commission on University Education in London, which was now sitting, and the recognition of the school by the Board of Education had also improved its position and status. Lord Ilkeston, also, in addressing the students at the close of the distribution of prizes, said that it was no inconsiderable advantage for the student to have his medical school attached to a hospital such as the Westminster, and the men he was addressing had the further advantage of being students in the school of medicine of London, which, in spite of its bad organisation, was perhaps the greatest school in the world owing to the large collection of clinical material that it offered for the study of medicine and surgery. In this school it was likely that changes would shortly take place, but he trusted that they would not take away from the hospital any of the instruction it at present gave so excellently in the art and science of medicine. The presence of students, he pointed out, raised the efficiency of a hospital and put their teachers through a valuable discipline. While he admitted that some hospitals in which there was no teaching had done excellent work, he was inclined to think that even these schools would have done still better had the work been carried out before the watchful eyes of a clinical class. If the connexion between medical schools and hospitals were removed the public would be injured most of all. A hospital did the public good in two ways: first, by relieving the applicant at its doors; and secondly, by benefiting the mass of the public who did not come into direct touch with the institution. In London with its dozen medical schools, the raising of the whole tone of medical practice, as the effect of the combination of hospital work with medical education, was prone to be overlooked; but in a provincial town the increased efficiency of the profession locally was very evident if a school were attached to the hospital. He hoped that as wise counsels prevailed in committees and conferences of governments, governments would see their way to bestow increasingly public grants on such institutions as the Westminster School of Medicine. Sir Robert Hudson, in proposing a vote of thanks to Lord Ilkeston, said that though he himself was merely a lay member of the hospital committee, he felt that under the conditions at present attaching to the application and disposal of hospital

funds, it behoved everyone concerned with hospitals to look squarely in the face this question of the financial future of the medical schools, which were engaged in supplying to the community a form of higher education, the gain of which was common to the hospital, the students, and the public at large. Sir William Allchin said that among the many reasons which tended to make the London School of Medicine great there was the important, though, perhaps, not very obvious, one that there was in London not only a wealth of clinical material such as that offered by no other city in the world, but also an active sympathy between those who managed the hospitals, on the one hand, and the students and those who taught on the other. Dr. F. de Havilland Hall, in seconding a vote of thanks to the chairman, said that his 35 years' intimate association with hospitals had taught him the inestimable value of having students in the wards. Indeed, he wondered how he would have got through his work without the stimulus of the student.

KING EDWARD'S HOSPITAL FUND.—The honorary secretaries of King Edward's Hospital Fund for London have received from the League of Mercy its contribution for the year 1910 of £18,000.

THE Nottingham Mothers' and Babies' Welcome will be the beneficiary of a grand matinée performance to be given at the Theatre Royal, Nottingham, through the generosity of Mr. Robert Arthur, on Thursday, Jan. 26th, at 2 P.M., when Mr. R. C. Carton's drama, *Liberty Hall*, will be produced.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.—Lectures free to all medical practitioners are held on Thursday afternoons at 4 o'clock. On Jan. 12th Mr. E. M. Corner will lecture on the Functions and Diseases of the Vermiform Appendix, and on Jan. 19th Dr. J. H. Thursfield will lecture on Purpura. In addition to these lectures each Thursday special post-graduate courses are held, for which fees are charged.

THE fifth annual dinner of the past and present students of the Royal London Ophthalmic Hospital will take place at the Imperial Restaurant, Regent-street, W., on Wednesday, Feb. 8th, at 7.45 P.M. Mr. Priestley Smith will preside. Each student is entitled to introduce two guests. Tickets (price 10*s.* 6*d.* each, exclusive of wine) may be had on application to either of the honorary secretaries, Mr. Arnold Lawson, 12, Harley-street, London, W., and Mr. J. Herbert Parsons, 54, Queen Anne-street, London, W.

THIRTY-SECOND BALNEOLOGICAL CONGRESS, BERLIN.—We announced this Congress in THE LANCET of Dec. 3rd, 1910, p. 1638. It will take place in Berlin from March 2nd to 6th, 1911. The President will be Geh. Med.-Rat Prof. Brieger. Forty-five papers have been accepted for submission to the Congress. Interesting references to radium are expected to be made, and Professor Marckwald of Berlin will deal with Radium from the Physico-Chemical Standpoint, and Professor Kionka of Jena will deal with Radium from the Biological Standpoint.

SOCIETY FOR THE STUDY OF INEBRIETY.—This society will hold its next meeting on Tuesday, Jan. 10th, at 4 P.M., in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W. The President of the society, Dr. Theodore B. Hyslop, will open a discussion on "The Influence of Parental Alcoholism on the Physique and Ability of Offspring." Each member and associate of the society is at liberty to introduce a visitor. The minimum annual subscription to the society is a nominal one of 5*s.* The honorary treasurer is Dr. G. Basil Price, 42, Welbeck-street, Cavendish-square, London, W., and the honorary secretary is Dr. T. N. Kelynack, 139, Harley-street, London, W.

## BOOKS, ETC., RECEIVED.

BALE (JOHN), SONS, AND DANIELSSON, LIMITED, London.
The Diseases of China, including Formosa and Korea. By W. Hamilton Jefferys, A.M., M.D., Univ. of Pennsylvania, Medical Missionary in China; Professor of Surgery, St. John's University; Surgeon to St. Luke's Hospital, Shanghai; Editor, *China Medical Journal*, and James L. Maxwell, M.D. Lond., Medical Missionary in Formosa; Chairman, China Medical Missionary Association Research Committee. Price 25*s.* net.
Lectures on Biology. By Dr. Curt Thesing. Translated from the Second Edition by W. R. Boelter. With the original Coloured and other Illustrations. Price 10*s.* 6*d.* net.

CHATTO AND WINDUS, London.
Herbert Fry's Royal Guide to the London Charities. Edited by John Lane. New and revised Edition—the forty-seventh. Price 1*s.* 6*d.*

CONSTABLE AND CO., LIMITED, London.
From Hausaland to Egypt, Through the Sudan. By H. Karl W. Kumm, Ph.D., Author of "Tribes of the Nile Valley"; "The Political Economy of Nubia," "The Sudan." Price 16*s.* net.

DULAU AND CO., LIMITED, 37, Soho-square, London, W.
University of London. Francis Galton Laboratory for National Eugenics. Eugenics Laboratory Memoirs. X. A First Study of the Influence of Parental Alcoholism on the Physique and Ability of the Offspring. By Ethel M. Elderton, Galton Research Scholar in National Eugenics in the University of London, with the Assistance of Karl Pearson, F.R.S. Second edition. Price 4*s.*
Eugenics Laboratory Memoirs. XIII. A Second Study of the Influence of Parental Alcoholism on the Physique and Ability of the Offspring. Being a Reply to Certain Medical Critics of the First Memoir and an Examination of the Rebutting Evidence cited by Them. By Karl Pearson, F.R.S., and Ethel E. Elderton, Galton Research Scholar. Price 4*s.*
Eugenics Laboratory Memoirs. XIV. A Preliminary Study of Extreme Alcoholism in Adults. By Amy Barrington and Karl Pearson, F.R.S., with the Assistance of David Heron, D.Sc. Price 4*s.*

LIPPINCOTT (J. B.) COMPANY, Philadelphia and London.
The Racial Anatomy of the Philippine Islanders, introducing New Methods of Anthropology. By Robert Bennett Bean, B.S., M.D., Associate Professor of Anatomy, the Tulane University of Louisiana, New Orleans, La. Price not stated.

MACMILLAN COMPANY, THE, New York.
The Citizen's Library. Child Problems. By George B. Mangold, Ph.D., Associate Director, Saint Louis School of Social Economy. Price 5*s.* net.

MARSHALL BROTHERS, LIMITED, London and Edinburgh. (THE MISSION TO LEPERS, Edinburgh (28, North-bridge); Dublin (Rogaland, Cowper-road); and London (33, Henrietta-street, Strand, W.C.))
Lepers: Thirty-six Years' Work among Them. Being the History of the Mission to Lepers in India and the East, 1874–1910. By John Jackson, F.R.G.S., author of "Mary Reed," "In Leper Land," &c. With a Short Introduction by the Dowager Marchioness Dufferin and Ava. New and revised edition. Price not stated.

PHARMACEUTICAL PRESS, THE, 72, Great Russell-street, London, W.C.
The Chemist's Annual and P.J.F. The Pharmacist's Diary and Year-book, 1911. Edited by John Humphrey. Price 5*s.* net.

SAUNDERS (W. B.) COMPANY, Philadelphia and London.
The Practice of Surgery. By James Gregory Mumford, M.D. Price 30*s.* net.

STANFORD, EDWARD, London.
Nigeria and its Tin Fields. By Albert F. Calvert. Price 3*s.* 6*d.*

THACKER, SPINK, AND CO., Calcutta.
The Treatment of Cataract. By Lt.-Colonel Henry Smith, B.A., M.D., M.Ch., Indian Medical Service. With Appendix by Captain A. E. J. Lister, M.B., B.S., F.R.C.S., Indian Medical Service. Illustrations by Dr. Derrick T. Vail, Professor of Ophthalmology, University of Cincinnati, &c. Price not stated.

UNIVERSITY PRESS, Cambridge.
The Cure of Surra in Horses by the Administration of Arsenic. By J. D. E. Holmes, M.A., D.Sc., Imperial Bacteriologist to the Government of India. (From "Parasitology," Vol. III., No. 3, October 22, 1910). Price not stated.

WARD AND CO., 34, Craven-street, Charing Cross, London, W.C.
Photography in Colours. A Text-book for Amateurs. With a Chapter on Kinematography in the Colours of Nature. By George Lindsay Johnson, M.A., M.D., B.S., F.R.C.S. Price 3*s.* 6*d.* net.

WHITAKER, J., AND SONS, LIMITED, London.
An Almanack. For the Year of Our Lord, 1911. By Joseph Whitaker, F.S.A. (Whitaker's Almanack.) Price 2*s.* 6*d.*

# Births, Marriages, and Deaths.

## BIRTHS.

CLARE.—On Dec. 26th, 1910, at Highcross-street, Leicester, the wife of T. C. Clare, M.D., F.R.C.S., of a son.

CRAWFORD.—On Dec. 28th, 1910 at Orchard Lea, Swanley, Kent, the wife of J. Dawson Crawford, M.D., of a son.

HOWLETT.—On Dec. 24th, 1910, at Springfield-road, Kingston-on-Thames, the wife of Bernard Howlett, M.R.C.S., L.R.C.P., of a son.

LEWIS.—On Dec. 30th, 1910, at Weymouth-street, W., the wife of Ernest E. Lewis, M.D., of a daughter.

POWELL.—On Dec 25th, 1910, at East Liss, Hants, the wife of Edgar Powell, Major, R.A.M.C., of a daughter.

RUSTON-HARRISON.—At Hill Cottage, Exmouth, on Dec. 26th, 1910, the wife of G. H. Ruston-Harrison, M.B., C.M., of a daughter.

SCOTT.—At "Tregenna," Staines, on Dec. 30th, 1910, the wife of Captain Norman Scott, I.M.S., of a son.

SIMPSON.—On Dec. 31st, 1910, at Coldharbour-lane, S.E., the wife of Patrick G. Simpson, M.B., C.M., of a son.

PEARSON.—On Jan. 1st, at Manor-place, Edinburgh, the wife of Charles Mowbray Pearson, M.B., F.R.C.P.E., of a daughter.

## DEATHS.

CLOETE-SMITH.—On Dec. 28th, 1910, at Westbourne-street, Hyde Park Edward Arnold Cloëte-Smith, M.R.C.S., L.R.C.P.

LIPSCOMB.—On Dec. 28th, 1910, in London, Edgar Richard Senhouse Lipscomb, L.R.C.P., M.R.C.S., aged 51 years.

SMITH.—On Nov. 29th, 1910, at Geelong, Victoria, Australia, Stephen Maberly Smith, M.R.C.S. Eng., L.R.C.P., L.M. Dub., aged 56 years.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## THE NOMENCLATURE OF THE SUPRARENAL PRINCIPLE.

WE note that in the "Year Book of Pharmacy" for 1910, the word "adrenine" is adopted generically for the active principle of the medulla of the suprarenal gland. This word, we believe, was adopted by the committee which published the B.P. codex but was rejected by the General Medical Council. In certain cases it seems to us the adoption of the word adrenine may misrepresent facts, for the extract is sold under various names, and the merits of each may be (and are) widely different. In the number of the "Year Book of Pharmacy" referred to there is an abstract of an article which appeared in THE LANCET of Oct. 2nd, 1909. The abstract is headed "Adrenine as an Emergency Treatment in Cases of Non-Corrosive Poisoning"; whereas, the original article in THE LANCET related exclusively to adrenalin, and the observations in the case were based entirely upon the use of "adrenalin." This seems to us to be a case where the use of a generic term which has not received complete acceptation may do a well-known active and efficient preparation an injustice.

## MEDICINE HAT.

THE *Daily Express* correspondent has informed his paper from New York on Dec. 24th last that Mr. Rudyard Kipling has written a letter to the inhabitants of Medicine Hat, Canada, on being informed that the city contemplated changing its name. "So far as I can make out," he writes, "the chief arguments for the change are that some United States journalists have some sort of joke that Medicine Hat supplies all the bad weather of the United States.' Medicine Hat is in the electoral district of Assiniboia West in the Province of Alberta, Canada. The United States is not without equally curious townships; for instance, it has two Medicines, Medicine Bow, Medicine Creek, Medicine Lodge, as well as a Medicine River, a Medical Lake, and a Medical Springs.

## SPARE MEDICAL JOURNALS.

*To the Editor of* THE LANCET.

SIR,—May I, on behalf of our doctors in the mission field, ask through your columns if the medical men and women of Great Britain who are in the habit of regularly getting medical journals, and who, after reading them, throw them aside, will kindly consider the needs of our medical missionaries in the foreign field? Any jou nals sent to Miss B. Gambier Parry, Bacton, Wokingham, Berks, will be very gratefully received and forwarded without delay to a missionary doctor.

I am, Sir, yours faithfully,

J. ANDERSON ROBERTSON,
Secretary, Medical Missions Department, S.P.G.

Westminster, Jan. 3rd, 1911.

## ROUND SHOULDERS.

ROUND shoulders are sometimes ascribed in boys to the common method of suspending the garments by braces. Although girls wear no braces, it is suggested that frequently their variously arranged waist-belts have the same evil drag on the shoulder tips as braces. In each case the trousers, drawers, or skirts are held up by buttons, the weight being imposed on the shoulders in the boy directly through his braces, and in the girl through the fact that her skirts are fastened to an under garment in itself dependent from her shoulders. In girls there is often added to the weight of their skirts an arrangement of elastic straps known as "stocking suspenders." These properly used are an admirable invention, but the result may be that the pull of these suspenders, added practically to all the weight of the child's clothing, is made to fall on the shoulder tips, and the shoulders being moveable may be influenced to a material and serious degree by a downward drag, the condition known as round shoulders being finally produced. We have had submitted for our inspection specimens of a new bodice-belt made by Mrs. Morison, of 26, South Molton-street, London, which render the use of braces in boys unnecessary and provide free play for the shoulders and chest of children of either sex. The bodice-belt is so constructed that whilst supporting the spine and lower abdomen it does not cause any strain on the chest and avoids any forward drag on the shoulder. Through its use the weight of the child's clothing is equally divided between the back of the shoulders, the spine, and the hips. The belt for the use of boys renders braces unnecessary, and is worn over the shirt, the chest and shoulders being left free by fastening the trousers through button-hole slips arranged in the garment for that purpose.

---

*A. B. S.* (*L.M.S.S.A.*).—Our correspondent's proposal that a serum prepared from cases of cancer that have undergone spontaneous cure might be valuable in the treatment of malignant disease has such obvious difficulties in the way of adoption that it must be only in rare instances and in exceptional circumstances that such a remedy could become available.

*E. T.* (*L.R.C.P. Ed.*).—Any case of cerebral hæmorrhage with slowly-spreading paralysis is interesting clinically, but a record in the absence of a post-mortem examination and without a description of the locality and extent of bleeding is too fragmentary for publication.

*D. M.*—Studies in Heterogenesis, 1904; Nature and Origin of Living Matter, 1905; Evolution of Life, 1907; all by Dr. H. Charlton Bastian.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

## A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1911:—

Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.
March 2nd–6th (Berlin).—Thirty-second Balneological Congress.
" 23rd (Paris).—First Congress of French Medical Journalists.
April (Berlin).—German Surgical Congress. (Thirty-ninth Annual Meeting.)
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
" 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.
" 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
" 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.
May 30th (The Hague).—International Congress on Opium.
May–October Dresden).—International Hygiene Exhibition.
May–October (London, Crystal Pa'ace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May–October(?) (London, Shepherd's Bush).—Coronation Exhibition.
June (Paris).—First Congress of the International Medical Association for the Prevention of War.
" (Los Angeles, Cal.).—American Medical Association.
June 5th–8th (Kolberg, Prussia).—Fifth International Congress of Thalassotherapy.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
July 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
August 15th–21st (Dublin).—Royal Institute of Public Health.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September (Brussels).—Exhibition of Fractures.
" (Turin).—International Congress of Pathology.
" (Genoa).—International Exhibition of Marine Hygiene.
Sept. 11th–15th (Berlin).—National Congress for the Study and Prevention of Infantile Mortality (*Gouttes de Lait*).
" 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
" 18th–23rd (Sydney).—Australasian Medical Congress.
" 18th–24th (Turin).—Fourth National Congress of Hygiene.
" 24th–30th (Rome).—International Congress on Tuberculosis.
" 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.
October (Cologne).—International Congress of Criminal Anthropology.
Oct. 1st–4th (Liége).—Second Congress of Alimentation.
Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
(Date not fixed) (Montreal).—Canadian Medical Association.
(Date not fixed) (Rome).—International Exhibition of Social Hygiene.
(Date uncertain) (Turin).—International Exhibition of Industry and Labour.

In 1912:—
Spring (London).—Second Optical Convention.
July (?) (Cologne).—International Congress of Nurses.
September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
" Visit of German Medical Men to America.
Nov. 22nd–29th (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

In 1913:—
(London).—Seventeenth International Congress of Medicine.
(Dresden (?)).—International Conference on Cancer.
(Washington).—Congress of American Physicians and Surgeons.
August (Buffalo).—Fourth International Congress of School Hygiene.

In 1914:—
(Vienna).—Third International Congress for Professional Diseases.

In 191b:—
(London).—International Prison Congress.
(London).—Imperial Exhibition (?)

THE following journals and magazines have been received:—*Contemporary Review, Cornhill, Burlington Magazine, M.A.B.* (*Mainly About Books*) *Christmas Number, The Child, Paris Médical, Critic and Guide, Monthly Bulletin of the Illinois State Board of Health, Medical Missions, The North American Review, School Hygiene, The Quarterly Journal of Medicine, The Century Magazine, The Military Surgeon* (*Washington, D.C.*), *&c.*

# Medical Diary for the ensuing Week.

## SOCIETIES.

**ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).**

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Jonathan Hutchinson, L. A. Dunn): at 5.30 P.M.

*Debate:*

On the Operative Treatment of Cancer of the Rectum. The following gentlemen will take part:—Mr. F. Wood Jones, Mr. F. Swinford Edwards, Mr. W. Harrison Cripps, Sir Frederick S. Eve, F.R.C.S., and Mr. H. F. Waterhouse.

The DEBATE will be continued on Wednesday, Jan. 18th, when the following gentlemen will take part:—Mr. A. Boyce Barrow, Mr. F. C. Wallis, Mr. P. Furnivall, and Mr. Lockhart Mummery.

Any other gentleman wishing to take part is requested to communicate with Mr. J. Hutchinson, 1, Park-crescent, W.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries: Albert Carless, James Galloway): at 8 P.M.

*Cases:*

Dr. J. D. Rolleston and Dr. N. S. MacNaughton: Familial Pigmentary Dermo-fibromatosis.

Dr. James Galloway: Congenital Heart Disease; Pulmonary Stenosis. And other cases.

*Communication:*

Dr. F. Parkes Weber and Dr. G. Dorner: A Case of Congenital Pulmonary Stenosis, with Special Consideration of the Nature of the Secondary and Blood Changes.

**MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.**

MONDAY.—8.30 P.M., Dr. J. Taylor: Some Ocular and Visual Conditions in Medical Cases.—Mr. P. Fleming: Some Cases of Medical Interest met with in Ophthalmic Work.

**SOCIETY FOR THE STUDY OF INEBRIETY, Rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W.**

TUESDAY.—4 P.M., Dr. T. B. Hyslop: The Influence of Parental Alcoholism on the Physique and Ability of Offspring (followed by a Discussion).

**HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.**

WEDNESDAY.—8.30 P.M., Mr. D'Arcy Power: Loose Cartilages and the Results of their Surgical Treatment.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.**

MONDAY.—College opens.

TUESDAY.—4 P.M., Dr. H. Campbell: Clinique (Medical). 5.15 P.M., Lecture:—Dr. C. O. Hawthorne: Instrumental Methods in the Estimation of the Arterial Blood Pressure.

WEDNESDAY.—4 P.M., Mr. R. P. Rowlands: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. R. W. Allen: Vaccine Treatment in Pulmonary Phthisis.

THURSDAY.—4 P.M., Mr. E. Pritchard: Clinique (Medical). 5.15 P.M., Lecture:—Dr. S. E. Dore: The Present Position of the X Ray Treatment of Ringworm of the Scalp.

FRIDAY.—4 P.M., Mr. L. Paton: Clinique (Eye).

**POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.**

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Etherington-Smith: Clinical (Lecture I.).

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Low: Plague.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Morton: Carbon Dioxide.

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery (Lecture I.).

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Saunders: Clinical (with cases).

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

**LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.**

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M. Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture: Sir Dyce Duckworth: The Significance of Albuminuria.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.**

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

# MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1910 were given in THE LANCET of Dec. 31st, 1910.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 will be ready shortly. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

## TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 1 0 | One Year ... ... ... | £1 5 0 |
| Six Months ... ... ... | 0 12 6 | Six Months ... ... ... | 0 14 0 |
| Three Months ... ... | 0 6 6 | Three Months ... ... | 0 7 0 |

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

## TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

## METEOROLOGICAL READINGS.

# An Address

ON

# THE INFLUENCE OF PARENTAL ALCOHOLISM ON THE PHYSIQUE AND ABILITY OF OFFSPRING.

*Delivered before the Society for the Study of Inebriety on Jan. 10th, 1911, in the Rooms of the Medical Society of London,*

BY THEO. B. HYSLOP, M.D., C.M. EDIN., F.R.S. EDIN.,

PRESIDENT OF THE SOCIETY; LECTURER ON MENTAL DISEASE AND MENTAL PHYSIOLOGY AT ST. MARY'S HOSPITAL MEDICAL SCHOOOL; LATE RESIDENT PHYSICIAN AT BETHLEM ROYAL HOSPITAL.

[AFTER some introductory remarks, in which Dr. Hyslop avowed the sympathy of the Society for the Study of Inebriety with the aims of the Eugenics Laboratory, he stated:—]

## THE PROBLEM.

I feel sure it is agreed that the problem we are met to discuss is not to be proved, or even advanced, by rhetoric, and, in my opinion, it is open to question whether it can be solved satisfactorily by statistics. *Does parental alcoholism—apart from parental degeneracy, which, together with a tendency to alcoholism, is heritable—influence the physique and ability of offspring?*

In order to answer this question we must, so far as is possible, first eliminate such sources of error as are due to the inclusion of side issues, indefiniteness of standards of alcoholism, health, and degeneracy, and we must correct our vague conceptions as to what really constitutes heredity. We ought also to equalise or exclude altogether such variations in environment as may possibly affect the germ-plasm of the parents or the offspring independent of the influence of alcohol itself. It is obvious, however, that it is well-nigh impossible to find a definite uniformity of phenomena on which to base statistics which shall be accurate in every particular. We cannot exclude all variations in environment, nor can we neglect the possibility of the intensification of degeneracy in successive generations due to a continuance of the same or different environmental defects.

In order the better to define our standards of parental degeneracy and alcoholism, it is important to note the sex, age at incidence, and evidences of inheritance, as well as the nature and degree of the defect. Needless to say, the environmental conditions should also be carefully noted. So far as the parental degeneracy and alcoholism are concerned, the Galton Laboratory researches have served the very useful purpose of bringing into prominence the *association*—in contradistinction to *causation*—of alcoholism and degeneration; but it must be confessed that the question as to which came first—the mental defect or the alcoholism—has not received such attention as is needed. As an asylum physician I am almost daily confronted with the difficulty of deciding as to which is cause and which is effect, and if, after full consideration of all the data available, it is well-nigh impossible to decide such an apparently elementary point, how much more difficult must it be to find sufficiently reliable data on which to base statistics! It is also to be noted that the tendency to degeneracy or alcoholism may be latent in the parent, and one or other of these defects may become manifest, owing to some accidental factor, either before or after the tendency has been transmitted to the offspring. This fact renders the question as to which came first—the alcoholism or the child—somewhat futile. At first I believed that parental alcoholism should invariably precede the birth of the child, but I have now come to see that such a stipulation would lead, not only to the suppression of half the truth, but even provide a source for error unless definite distinction were made between parental alcoholism *per se* and parental degeneration plus a psycho-neurotic tendency to alcoholism.

## ALCOHOLISM AT CONCEPTION.

The occurrence of conception at some festival season, when acute alcoholism is rife, has provided some investigators with data for consideration. The assertion that alcohol at festivals is the source of imbecility in offspring is as yet, however, unproven. Undoubtedly, there may be an increase in the number of conceptions on such occasions, but I am not aware of any statistics which take into account the relationship of the alcohol to degeneracy in the parent, and the possibility of any ill results to the offspring being due to direct heredity has not, so far as I am aware, been adequately considered. In this connexion it must be noted that we know but little of the influences, alcoholic or otherwise, which determine conception; and, moreover, the parents are apt to shelve their responsibilities in such matters, and attribute defects in their offspring to some accidental or even fanciful cause. Certain it is that many of the poorer classes attribute the largeness of their families to the abuse of alcohol and the consequent loss of control and other considerations.

The earlier researches of Laitinen,[1] to which reference is made by the same observer in his Norman Kerr lecture[2] and further contribution to the proceedings of the last International Congress on Alcoholism, have been very freely and exhaustively criticised by others. That he made no distinction between parents, one of whom drank, or both of whom drank, provides Professor Karl Pearson and Miss Elderton with matter for self-congratulation, in that they themselves distinguished between the father and mother, and arrived at the conclusion that the drinking of the mother had more influence than the drinking of the father, and that, slight as was the effect, since it influenced girls more than it influenced boys, it was unlikely to have been due to toxic action on the fœtus. That the latter observers carried their observations a few steps farther than did Professor Laitinen cannot be denied, but, needless to say, this fact does not in itself render their conclusions any the more valid. Laitinen's previous researches on the effects of small quantities of alcohol on animals, and the degeneration which he claimed to have found in their offspring would, if correct, appear to have more direct bearing on the subject, inasmuch as it is not probable that the offspring inherited a parental neurosis or psychosis to which the effects of alcohol had been added and transmitted as such to the offspring. For our purposes we must merely take note of Laitinen's statement that the number of young of those animals that received alcohol was somewhat larger, but much weaker, than in the case of the young of animals not treated with alcohol. The truth of this statement will doubtless be fully investigated, and upon its verification much must necessarily depend.

For a long time past I have in many instances attributed mental and physical defects to parental alcoholism, but I must now confess that, after careful consideration of the data so much discussed by the members of the Eugenics Laboratory—Sir Victor Horsley, Dr. Saleeby, Dr. Basil Price, Dr. Demme, Dr. Bezzola, Dr. Laitinen, Dr. MacNicholl, and many others—I have endeavoured to discard my previous conceptions, and I have sought diligently for an instance of defect which I could honestly convince myself as being due solely and entirely to parental alcoholism. Formerly I regarded epilepsy, some forms of insanity, mental enfeeblement and defective inhibition, deaf-mutism and stunted growth, as being mainly due to parental alcoholism. All these conditions, however, fall under the category of defects in what has been aptly termed the "general controlling determinant," and I have as the outcome of much clinical experience imagined I could diagnose parental alcoholism from the symptoms evidenced in the offspring. Now I feel that I cannot truly satisfy myself that in any one case there had not been also other factors than alcohol at work, and that the symptoms in the offspring might possibly have been due to the direct inheritance of a neuro-psychosis as well as alcohol.

It is obvious that instances of defective germ plasm in the stock—which may evidence itself by alcoholic tendencies throughout the stock—are instances of heredity pure and

[1] Lecture delivered at the Anti-Alcohol Congress in Stockholm, 1907.

[2] See British Journal of Inebriety, October, 1909; and "Contribution to the Study of the Influence of Alcohol on the Degeneration of Human Offspring" (Proceedings of Twelfth International Congress on Alcoholism, 1909).

simple, and they ought, for the satisfactory solution of the problem before us, to be rigidly excluded. Such a process of exclusion, however, might result in the elucidation of but half the truth, and, as we shall see presently, in order to obtain the whole truth, the question does really involve the consideration of the degenerate and the problems of heredity.

The Eugenics Laboratory Memoir, No. X., did not profess to deal with the direct heredity of alcoholism. It concerned itself only with the offspring of the alcoholic as children. Of the results that drinking produces in the offspring it is stated with a certain degree of truth that "alcoholism in the parent may, like insanity, be the somatic mark of a defective germ plasm in the stock. The child is defective not because the parent is alcoholic, but because it is the product, like the parent, of a defective germ plasm. The child may be physically and mentally fit, and yet, when adult, exhibit alcoholic tendencies."

This contention does not include, or even refer to, the almost accepted assumption that alcoholism in the normal, as in the degenerate, parent is apt to lead to earlier alcoholism or degeneracy in the offspring. At present my experience leads me to the belief that parental alcoholism accentuates the downward trend, and with each successive generation the period of exemption from alcoholism and degeneracy is shortened, so that the offspring become alcoholic or degenerate at a relatively earlier age.

Doubtless, however, this will form the subject for some future memoir, and possibly it may be ascertained whether parental alcoholism in the degenerate does or does not modify, diminish, or intensify the evidences of defective germ plasm in the stock—i.e., does parental alcoholism alter the character or degree of the inherited degeneracy in the offspring? It would seem to me that alcohol as a complementary factor to parental degeneracy does aid in the devolution of the stock, and it is upon families which are prone to degeneracy that alcohol appears to put the finishing touches and renders the physique and ability of the offspring more and more unsatisfactory with each successive generation.

Certain it is that nature does not permit any prolonged departure from its laws of health and the trend of evolution, as shown by the tendencies for neuroses and psychoses to spread and ultimately wear themselves out in the course of time and with successive generations. This law holds good so long as other complicating factors, such as alcohol, do not add to the burden, and by attacking the more or less attenuated neuroses or psychoses, keep them alight and thereby frustrate the efforts of nature to render them abortive. Alcohol, as we all know, will readily set alight and determine the existence of a neurosis or psychosis which might otherwise be on the wane; and not only does it affect the individual and intensify his degeneracy, but it is also open to belief that it renders the offspring more liable to suffer from the transmission of such degeneracy, not only in its parental intensity, but also to be manifested at an earlier age in the progeny.

In the last report from the Galton Laboratory claim is made that alcohol is, in its *pernicious* forms, consequent on, and not antecedent to, mental defect. This may be true, and if rightly understood and supplemented by an account of the influence of alcohol in intensifying an already existing nervous defect, it can do no harm to the cause of temperance. That it is the aim of the previous memoir to prove that alcohol may be taken with impunity no one with any sense of justice will contend; nor need it be imagined that alcohol is in any sense regarded as being capable of aiding the onward and upward trend of biological evolution. Referring as it does to pernicious forms of alcoholism, it is, of course, hardly likely to take cognisance of any statistics based upon the consumption of one glass of beer per day.

"One man's food, another man's poison," refers to alcohol as much as it does to any other article of consumption, and it is indeed difficult to differentiate the degrees of alcoholism. Another matter about which there has been much contention, yet which has not yet been referred to in its true bearings, is the fact that in asylum practice it is comparatively seldom that we find the various lesions so common to alcoholism in the sane. The reason for this may possibly be that alcohol selects for attack the least stable of the bodily systems in a given individual. The system may be, by its inherent weakness, more susceptible to attack, or it may be less able to eliminate from its substance the effects of toxic action. Whichever way we look at the question, however, it must be conceded that the pathological findings in the insane are in favour of the Galton theorists, and it is difficult to conceive any other explanation of the selective action of alcohol other than by the inherent weakness of the nervous system, as is found in inherited degeneracy.

It is impossible for me to deal with all the points at issue both with regard to parents and offspring and their environmental relations, so I conclude by stating that in my humble opinion it would serve our purpose best could we but find well-defined and accurate instances in which defect in the child could be proved to be due to parental alcoholism without the aid of any other causal factor, such as degeneration or faulty environment. Until this can be done, and until we can multiply such instances, any statistics we may compile can only help us to make hazardous half-guesses, which may lead to misinterpretation and the spreading of doctrines and lines of action which may be for the good or ill of the community.

## General Conclusions.

1. It is easy to make a tangle of a skein of silk, and nothing is easier than to employ destructive criticism to any theory which may be propounded in reference to the influence of parental alcoholism on the physique and ability of offspring.

2. The theory briefly stated is, Does parental alcoholism (of a pernicious kind)—apart from parental degeneracy, which, together with a tendency to alcoholism, is hereditable—influence the physique and ability of offspring?

3. It is practically impossible to exclude side-issues, variations in standards of health, alcoholism, and degeneracy from consideration, and we have as yet but imperfect conceptions as to what is meant by heredity. Hence we cannot obtain sufficiently accurate data for statistical purposes.

4. The *association*—in contra-distinction to *causation*—of alcoholism and degeneration in the parent is insufficiently understood, and the difficulty in distinguishing between cause and effect, both in the parent and offspring, is so great that the decision must be frequently mere guesswork.

5. The present problem requires that parental alcoholism shall precede conception or the birth of the child; whereas, in the transmission of a psychoneurosis by direct inheritance, the parental alcoholic tendency may be latent, and not come into evidence until after the birth of the child. This necessitates complete differentiation between the two series.

6. Alcoholism would appear to be responsible for a relatively greater number of births than would health or degeneracy without alcoholism, and there appears to be some evidence derived from experiments on animals treated by alcohol that their young, although in greater number, were much weaker.

7. Epilepsy, some forms of insanity, defective inhibition and mental enfeeblement, deaf-mutism and stunted growth, although instances of what has been aptly termed the "general controlling determinant," and transmitted by direct heredity, are apt to be not only intensified in the offspring, but they make their appearance at a relatively earlier age, when parental alcoholism has been an additional factor.

8. Parental alcoholism does appear to accentuate the downward trend of inherited psychoneurosis, and with each successive generation the period of exemption from alcoholism and degeneracy becomes shortened, so that the offspring become alcoholic or degenerate at relatively earlier ages. Alcohol would in this way act as a complementary factor to parental degeneracy, and aid in the devolution of the stock.

9. The inheritance of a psychoneurosis (which would tend to diminish in severity with each successive generation, and with the introduction of new correcting influences through marriage) becomes intensified and prolonged when alcoholism becomes a complicating factor. In this way the psychoneurosis is kept alight through a greater number of generations.

10. The conclusions arrived at by the Galton Laboratory School of Eugenics and their critics deal with part only of the general question at issue, and when further investigations shall have demonstrated the influence of parental alcoholism on parental degeneracy, and the combined influence on the physique and ability of offspring, we shall be better able to speak with authority for the guidance of the community.

# An Address
ON
# THE RÔLE OF SEPSIS AND OF ANTISEPSIS IN MEDICINE.

*Delivered at the Opening of the Session of the Faculty of Medicine of McGill University, Montreal, on Oct. 3rd, 1910,*[1]

BY WILLIAM HUNTER, M.D. EDIN., F.R.C.P. LOND.,

PHYSICIAN AND LECTURER ON PATHOLOGY TO THE CHARING CROSS HOSPITAL, LONDON; PHYSICIAN TO THE LONDON FEVER HOSPITAL.

[AN introductory section of the address dealt with the objects of medical education.]

## MEDICAL SEPSIS AND MEDICAL ANTISEPSIS.

After these prefatory remarks regarding the objects of your present studies, I pass on to the subject which I have selected as the special theme on which I desire to address you to-day. That theme is the great part played by Septic Infection—prevalent, potent, easily observed and accessible to treatment, nevertheless continuously overlooked and neglected—as an important cause and complication of a whole range of medical diseases. I have selected it not only because of its great practical importance to you in your medical work in after life, but also because the story of its recognition as a great factor in causing disease illustrates in a striking way the truth of what I have just said about the importance of small things in medicine—their observation and interpretation.

For it was while seeking to throw light on the origin and meaning of a piece of blood pigment present in an organ in the first case I ever examined for curiosity's sake, that I stumbled upon the chief subject and interest of my life's work—namely that of anæmia. And it was while observing as fully as I could all the features of the first case of anæmia which I ever studied clinically that I came upon the curious facts that ultimately led me to recognise the importance of sepsis in medicine not only in producing anæmia, but also many other medical affections.

I spent some five years (1885–1890) in experimental and pathological work in trying to explain the meaning of that piece of pigment, and some ten years (1890–1900) in trying to explain the features presented by that one clinical case. And *then I saw*, but not till then—what I have since endeavoured to describe in various papers from 1900 onwards up to the present time regarding the rôle of sepsis in medicine and the importance of oral sepsis as its chief cause.

I desire now to draw your attention to the great province concerned with the action of septic infection in medicine as one deserving your attention as much as sepsis in the great domain of surgery. Like the great North-West Territories of your own land, this province of sepsis in medicine has been with us all the time, awaiting only a fitting recognition and exploitation of its great resources. It is, as yet, but sparsely populated; workers and settlers in it are but few, though they have been steadily drifting into it during the last ten years, first one by one and more recently by scores and hundreds; and already many of these have sent back encouraging and even glowing accounts of its resources. But the field is so large and the work in it is so great that its resources will not be fully exploited till the workers in it include the whole profession, prepared, if necessary, to identify themselves with it by taking the name of this great province of their work. For like many of your territories, it has remained until now without even a definite name. That name I propose now to give it, so that even if you pass it by and are not attracted by its prospects you will at least from henceforth know what portion of the great domain of medicine is meant by it.

Time was, and I am old enough to recall it, when the greatest honour that could be paid a surgeon was to term him a brilliant operator and to expatiate upon the rapidity with which he could carry out a particular operation. Time is, and long has been, when the title which a surgeon is proudest of is that of an "antiseptic surgeon." Possessing the knowledge, the training, and the experience that entitle him to that name, he knows that it is possible for him to become a successful surgeon; he is a worker in the field of "*antiseptic surgery*."

Time, in my opinion, has now come—or if not already come is fast approaching—when the title of "Antiseptic Physician" will become equally distinctive of a good doctor; when it will be equally honoured and honourable as that of "Antiseptic Surgeon" now in the case of the surgeon; when the knowledge and outlook which it implies in regard to the importance of sepsis in medicine will be deemed one of the highest qualifications which a good doctor could possess; when, in short, "Antiseptic Medicine"—the fight against sepsis in medicine—will come to have as distinct a meaning in relation to sepsis in medicine as "Antiseptic Surgery" has in relation to sepsis in surgery; when a knowledge of the principles and practice of "Antiseptic Medicine" will be deemed as essential and necessary to the physician as a knowledge of the principles and practice of antiseptic surgery is now essential to the surgeon. What these principles are it will be the purpose of this address to bring to your notice. They are deeply rooted in the knowledge and experience which it is the purpose of your present studies to give you.

## PRINCIPLES OF ANTISEPTIC SURGERY.

The word "principle" which I have here employed is in common use in medicine. We speak of the principles of surgery, of medicine, of treatment, of pathology. In the sense in which it is thus employed the word means the essentialness, essential part of, important part, quintessence, pith, backbone, marrow, heart, and soul of these subects. It includes not only the *facts*, but also some reference to the *reasoning*-grounds, way of thinking, reflection, conclusion, judgment, motive, springs of action that determine the action we take upon these facts.

If any of you, even the youngest, were asked by a layman what the "principles" of antiseptic surgery were he would probably not be able to give the whole facts and the whole chain of reasoning, observation, and experience on which the practice of antiseptic surgery is based. Even with the limited experience he possesses he would, if he were a wise student, be more likely to reply that the chief principle of antiseptic surgery is, of course, that organisms cause fever, inflammation, suppuration, &c., and hence the necessity for all the surgical precautions and the elaborate surgical ritual witnessed from day to day in the surgical work.

The motives and the grounds for antiseptic surgery are very clear and obvious, and are demonstrated daily in his surgical work. They are thrust upon his notice ever moment of his surgical life; they are driven into him by the whole teaching and surroundings of his surgical work. He lives in a very atmosphere of worship of Antisepsis; he conducts services at her shrine; he places offerings of clean hands and a pure antiseptic conscience and behaviour on her altars. Figuratively, if not actually, he sees in flaming characters written above the doors of her Holy of Holies—the operation theatre—the words—

"Abandon Sepsis all ye who enter here."

And even if this escapes his notice the janitor who guards the door is there to remind him:

"Put on thy shoes, for the place on which thou enterest is antiseptic ground."

Is this ritual connected with surgical antisepsis overdone? Are its surroundings too ornate—its practice too ceremonial, its services too elaborate, its vestments and mitres too striking? I think not, *if* the surgeon or doctor carries these antiseptic principles into practice wherever he meets with sepsis. On the contrary, they are educational to a degree. No shrine in connexion with modern scientific medicine and practice appeals more to the imagination than that constituted by a modern operating theatre. In no department of the whole field of modern medicine are its services to humanity so faithfully, so loyally, so scrupulously and exactly rendered as in that spot dedicated to antiseptic surgery.

What is the object of this whole elaborate ritual of observant practice? It is designed primarily for one great purpose—to prevent the access of organisms into the wounds which the surgeon has necessarily to make in the course of

[1] The delay in publication of the address has been due to the absence of the author in America and Canada for some time after its delivery.

his surgical work. To avoid such an occurrence—such a catastrophe, as he would deem it—the surgeon takes every possible precaution that knowledge and experience suggest to him. No precaution is too minute, no duty, however trivial, appears to him as such in the attainment of his great object. He renders these services, he observes these precautions as faithfully and as strictly in the case of the outcast admitted from the poorest slum as he would to the highest personage in the land.

In the early days of antiseptic surgery the ritual was different, for the principles underlying it were also different. It was at first sight thought that organisms of any kind might produce the untoward results which the surgeon feared; hence the first observances of antiseptic surgery—the use of spraying during the operation and the elaborate and repeated dressings necessitated during the subsequent healing of the wound.

It is now known that the organisms which the surgeon has most to fear are not those in the air, but those present (staphylococci and streptococci) on the patient's skin, or on his own fingers, or on the instruments which he employs. His procedure is therefore now directed primarily, not against the organisms of the air—although precautions against these are involved in the arrangements he makes for the ventilation of his operating theatre; nor yet primarily against the introduction of organisms from the walls and floors, although that source is also scrupulously kept in view in the plans he accepts for his floors and ceilings and walls, and in the ritual he observes in his work.

The full force of his precautions is directed against the introduction of septic organisms into his wound conveyed by his own fingers or those of his assistants, or by his instruments. If he has an untoward result where he confidently expected a successful one, if fever occurs or his wound suppurates without obvious cause, his suspicions, if he is a good surgeon, would probably fall first upon his own fingers, secondly upon those of his assistants, thirdly upon his instruments, and fourthly, or lastly, upon the air in the theatre. If he were a bad surgeon the order of suspicion would be reversed.

You will note that the whole procedure of the antiseptic surgeon is directed against the introduction of organisms into the body as the result of his own operation; or, at least against their conveyance from places where they are already present—e.g., the intestine—into cavities such as the peritoneum, where their effects might be serious or fatal. His responsibility, in short, so far as preventing the access of organisms into the body, begins and ends there. If they gain access through his wounds, through the failure of any precautions on his part, he is responsible, and no one feels this responsibility more than he does. If, however, the organisms are already in the body, as they frequently are in abscesses and suppurations connected with the bones, joints, stomach, intestines, liver, kidney, and other organs which he is called on to relieve by operation, he is only responsible for seeing that, so far as he can help, the organisms shall not be conveyed by his procedure into adjacent parts. He is not—he considers—responsible for their original access to the parts where they are causing trouble. That is a *medical* or *pathological* matter with which he is not primarily concerned, and with which he cannot deal. And yet unknown to him, and unnoted by him, he may be allowing his patient to retain a degree of sepsis (in the mouth) which would receive his immediate attention were it found anywhere else (e.g., Cases 1–6).

### SEPSIS IN MEDICINE.

I have dwelt on this point—the extreme ritualistic regard which the surgeon shows towards sepsis in surgery; for I wish to contrast it with the attitude of the medical profession towards the same (staphylococcal and streptococcal) sepsis in medicine—i.e., in medical diseases.

That attitude is a very curious one, as will presently appear. If a doctor were asked what it was he would probably say that it differed in no way from that shown towards it in surgery. He was as keen to discover and remove sepsis and its various suppurative and necrotic effects in the domain of medicine—e.g., in connexion with the throat, pharynx, stomach, duodenum, gall-bladder, liver, cæcum, appendix, colon or rectum, pelvis of kidney, the brain, the pleura and the lungs, the glands, &c., or failing the presence of actual pus he was as keen and observant about the presence or absence of streptococci in the blood in cases of obscure blood poisonings, septicæmias, ulcerative endocarditis, &c., as the surgeon was in the surgical domain. He could even point out that so much was this the case that these various regions of the body had been largely divided up among specialists, who devoted the greater part of their time to dealing with the various affections of these parts—among these affections septic infection being one of the commonest and most important. In short, his attitude towards sepsis in medicine, he would maintain, was precisely the same observant one as he was taught to show towards it in surgery. The only difference between the two cases, he might point out, was the unfortunate one—viz., that the sepsis he found in medicine was not so easily got at or so easily removeable as it happily was in the domain of External Surgery. But, as we saw, the regard which the surgeon shows towards sepsis in the domain of surgery is not confined to its removal when present. It has another and far greater object—namely, its prevention. It is not so much in the removal as in the prevention of sepsis that surgical antisepsis has won its great triumphs.

### APPARENT RÔLE.

If the doctor were asked how the matter stood with regard to the *prevention of medical sepsis*, he would probably say that that was a matter he unfortunately could not control. These septic suppurations unfortunately occurred in medicine as complications of various medical diseases; in fact, they were often the essential features of these diseases, or actually constituted them—perforations, appendicitis, empyema, liver abscess, cholecystitis, glandular abscesses, septicæmia, ulcerative endocarditis, &c. The occurrence of these grave septic conditions, whether local or general, depended upon the state of health of the parts affected or of the body as a whole; and the factors concerned in giving rise to them were therefore as many and as various as the many and various local or general factors affecting the health of the particular organ, or of the body as a whole. Staphylococcal and streptococcal organisms were always in the body—e.g., the intestinal canal. It was unfortunately impossible to prevent them getting access now and again into other organs or into the blood. In any case, however common the above-named septic conditions might be, they were, after all, rare in comparison with the medical diseases with which he had to deal, of which they were only occasional complications or sequelæ. When they did occur they were matters for the surgeon—not for him. He found sufficient scope for his own work among the more purely medical complaints and illnesses of his patients—the various conditions of general ill-health presented by his patients; the malnutrition, the tonsillitic, naso-pharyngeal and glandular troubles of younger children; the dyspepsias, indigestions, gastric and duodenal ulcers, intestinal catarrhs and ulcerations, and liver disturbances of his older patients; their subacute and chronic rheumatic troubles; the simpler anæmias of young girls which usually yielded easily to treatment, although they sometimes were curiously resistant to treatment; the much more severe and troublesome anæmias of the middle and older periods of life; the multitude of their nervous complaints; their fevers of known nature (influenza or scarlet fever, diphtheria, typhoid, measles, &c.), and their complications; still more, the fevers of unknown or obscure nature which they occasionally suffered from and were so troublesome both in diagnosis and in treatment.

These and other affections of a like kind were numerous and troublesome enough to occupy all his time and call for all his powers of diagnosis and all his skill in treatment by appropriate medicinal and dietetic measures. They took in the medical sphere the place and importance that sepsis and its prevention took in the surgical sphere.

Complications of a septic nature sometimes occurred in connexion with some of them. These called for the help of the surgeon. To the surgeon septic infection was an all-important factor of disease. The doctor, worried to death with the multitudinous complaints of his patients and the apparently multitudinous and obscure causes underlying them, might often feel envious—if he cared to be so—of the surgeon's easier task in having to deal so much and so successfully with the removal or prevention of one well-defined infection—septic infection. If only he were able to prevent the causes of his patient's troubles as quickly and as effectively as the surgeon prevents or gets rid of sepsis, his

work in medicine, he might well say, would be a simpler and more interesting work both to his patients and to himself than it now is. Alas, however, from the point of view of prevention, the medical diseases with which he had to deal arose from many causes connected with the habits of life and surroundings of the patients—difficult to ascertain, and when ascertained not so easily preventable or removeable as the great factor of septic infection in surgery.

Sepsis in surgery, its action, prevention, or removal, was the greatest "principle" of pathology and practice with which the surgeon had to deal. Sepsis in medicine was a causal factor of altogether subsidiary importance; it was only one of many others. Even when it was present it was in most cases, if not in all, only a complication of other diseases, not its primary cause. It was an accident—a "terminal complication" of some other and more important disease.

### ACTUAL RÔLE.

Now, it is with this whole conception of the sphere of activity and importance of sepsis in medicine that my whole work for many years joins issue. What I wish to say to you to-day is that the above conclusions regarding its importance do not in my experience represent even approximately the actual pathological and clinical facts of the case.

In my clinical experience septic infection is without exception the most prevalent infection operating in medicine, and a most important and prevalent cause and complication of many medical diseases. Its ill-effects are widespread and extend to all systems of the body. The relations between these effects and the sepsis that causes them are constantly overlooked, because the existence of the sepsis is itself overlooked. For the chief seat of that sepsis is the mouth; and the sepsis itself, when noted, is erroneously regarded as the results of various conditions of ill-health with which it is associated—not, as it really is, an important cause or complication.

The causal connexion between the two sets of processes—the sepsis and its ill-effects—can be demonstrated by the simple expedient of removing the sepsis, and noting the striking effect which the removal has upon the existence, character, and intensity of the ill-effects. The ill-effects referred to include in individual cases every one of the diseases described in the foregoing section, and regarded as essentially medical in their character—viz., the general ill-health, dirty, sallow complexions, the indigestions, the gastric and intestinal troubles, the anæmias which resist treatment; tonsillitic, pharyngeal and glandular troubles of children; the chronic rheumatisms; obscure fevers, and blood poisonings, &c.

The effects are not the same in all cases, any more than are the effects of septic infection in surgery or those of tuberculous infection in medicine. They affect sometimes one system and sometimes another, in different degrees according to the individual susceptibility, just as a chronic tuberculous infection may in one case affect the glands of the neck, in another the joints, in another the bone, in another the lung, in another the meninges, in another the peritoneum, and in another it may affect them all.

So with this septic infection in medicine, the effects fall sometimes more on the tonsils, pharynx, or glands of the neck; sometimes more on the stomach, intestine, and colon; sometimes more on the blood, causing anæmia, purpuras, chronic septicæmias, obscure fever; sometimes more on the joints, causing so-called rheumatic trouble; sometimes more on the nervous system, or on the kidneys; and sometimes it falls in a fulminating way upon the blood as a whole, causing a general infection with streptococci with or without infective endocarditis.

The sum-total of ill-effects which it produces—of the ill-health and incapacity occasioned by its presence—is very great. It is greater in my observation than that produced by any other single factor in medicine, or by any other single infection operating in general medicine.

Sepsis in medicine therefore ranks, in my experience, as the most prevalent and potent infective disease in the body. It therefore deserves the particular attention of the whole profession, as much as it has hitherto received their particular neglect. It requires this attention at the hands of every branch of the profession. But it concerns especially the medical profession—the doctor whom the patient first consults. The responsibility for first detecting its existence, or realising its significance as a potential cause or complication of the patient's disease, or of applying the first measures of treatment—all devolve upon him. It is his opinion and interpretation that will determine the degree of importance which the patient will attach to his condition. If he belittles what he sees, or, what is even more common, if he fails to observe by close examination what lies before his eyes, the patient will not receive the advice or treatment he needs, and he will not allow others to give it to him.

### "ORAL SEPSIS."

In the foregoing sketch of the chief spheres of the doctor's work and interest I omitted any reference to one other portion of the body which constantly comes under his observation—indeed, more often than any other; I mean the mouth. This omission was intentional on my part. The cases presently to be described—which could be multiplied by thousands and tens of thousands coming under the daily notice of doctors—illustrate how constant this omission is in practice.

There is no part of the human body more commonly looked into by the doctor than the mouth. He looks at the tongue of every patient he sees, and learns much from its condition. It is notoriously a very unruly member, in more ways than one. It constantly "gives away" its owner in the ordinary affairs of his life, and it does the same in the matter of his diseases. For it yields the doctor most instructive and important information regarding the bodily health—the condition of digestion and the general health.

When looking into the mouth of his patients the doctor has often occasion to note incidentally the presence of defective or decayed teeth, as a general accompaniment and apparently as a part result of the poor health, poor nutrition, or wasting diseases from which they suffer. These defects of the teeth are so common that he has ceased to worry about them. He has often asked his patients, How can they expect their digestion to be good? What else but indigestion can they expect if they will not have their "teeth put in order" by the dentist, or get the dentist to supply new ones. How can they expect to masticate their food properly with such defective teeth? But, as he may sorrowfully add, patients are "hopeless" in this matter; they will not "attend to" their teeth; not only so, they are also actually "touchy" on the subject. The patient is quite willing to describe and discuss with the doctor all his other troubles and complaints, to which, as he says, he is a "martyr"—his indigestions, headaches, liver troubles, his rheumatism, his gout, and his "neuritis." But the subject of his teeth is his own affair—one between himself and his dentist. And the doctor regards it as such. "It is a matter of teeth and dentistry," with which he cannot deal.

What I desire to impress upon you students, and all students entering the profession, and all those already engaged in the practice of the profession, is, it is "not a matter of teeth and dentistry." It is an all-important matter of sepsis and antisepsis that concerns every branch of the medical profession, and concerns very closely the public health of the community. It is not a simple matter of "neglect of the teeth" by the patient, as is so commonly stated, but one of neglect of a great infection by the profession—a great infective disease for which the patient is not primarily responsible any more than he is responsible for the contraction of typhoid fever or tuberculosis. The condition referred to is that to which I have given the name of "oral sepsis."

The title "oral sepsis" was first introduced into medical literature in a paper entitled, "Oral Sepsis as a Cause of Disease."[2] My object in seeking for a special name, and after consideration in creating this one, was to emphasise the great fact that it is not the absence of teeth but the presence of sepsis, that it is not dental defects but septic effects, that it is not defective mastication but the effective sepsis associated with such dental defects or often present in conditions of gingivitis apart from such defects, that are responsible for the ill-health associated with "bad" mouths.

The second object was to emphasise the importance of the infection caused by staphylococcal and streptococcal organisms, as distinguished from the purely saprophytic infections in which the mouth abounds; or the temporary presence of specific organisms—e.g., typhoid, tubercle, pneumonia, &c.

The subject of "oral sepsis," as I designated and defined

[2] Brit. Med. Jour., July, 1900.

it—namely, the septic lesions of streptococcal and staphylococcal infection found in the mouth—belongs to no one department of medicine or surgery. It is common ground on which the general doctor, physician, or surgeon; the throat, nose and ear, and eye specialist; specialists in children's diseases, in stomach diseases, in blood diseases, in "rheumatic" diseases, in fevers, in skin diseases, in nervous and mental diseases, and, lastly, the dental surgeon, all meet on terms of equal responsibility. In its earliest manifestations no special knowledge is required to deal with it; a sound grasp of the principles underlying antisepsis alone is required. Unfortunately for the patient, it is precisely this grasp which I grieve to say is wanting.

One would think poorly of a surgeon or doctor who declined to take the responsibility of treating a follicular (that is, a "septic") tonsillitis, but insisted on handing over the case to a throat specialist, or who allowed a patient to suck continuously a number of septic sores on his finger. I think no less poorly of any doctor or surgeon who declines to make himself responsible for the treatment of much of the oral sepsis presented by many of his cases. For this is what patients are constantly doing. Wherein consists the pathological difference between a follicular tonsillitis and a foul, septic suppurating condition of the gums, with deposition of calcareous "crusts and scabs" (so-called tartar), covering and hiding septic wounds and ulcers—loaded, as microscopic examination shows, with staphylococci and streptococci. None whatever, except that the latter is exceedingly common and the tonsillitis is comparatively rare. The pathological condition in both is the same—namely, sepsis. Moreover, it is a sepsis as easily recognised and much of it as easily removed in the case of the one as in that of the other, and the more urgently requiring to be removed since it is more important as a potential disease factor than any other source of sepsis in the body.

But, it is urged, the condition is so common that it is impossible either to prevent it or to deal with it successfully; further, the ill-effects are few and rare compared with the wide prevalence of the condition. As I originally showed (1900), and my further experience of the last ten years, supported by that of many others, fully demonstrates, the ill-effects are both common and grave. That they are not more common is due solely to the great resisting power possessed by the mucosa of the mouth and gums.

This matter of oral sepsis is, therefore, of urgent importance in relation to the whole multifarious and widespread group of affections—medical, surgical, and dental—caused by the actual presence or toxic action of pyogenic organisms (staphylococci and streptococci).

My clinical experience satisfies me that if oral sepsis (and naso-pharyngeal) could be successfully excluded, the other channels by which "medical sepsis" gains entrance into the body might almost be ignored. Sepsis as an important and prevalent cause of disease in medicine would almost cease to exist, instead of being, as in my judgment it is at the present time, a more important and prevalent cause of disease in the domain of medicine than it is in that of surgery. Time was when the positions were reversed—when sepsis was so prevalent in the surgical wards that it overflowed into the medical wards in the form of some of its effects—for example, amyloid disease of kidney and liver and intestine. Now the relations are otherwise. In the form of the various affections above mentioned the greatest variety and most severe manifestations of sepsis and its effects are, in my experience, to be found in medical wards, whence they overflow (in the form of appendicular, gall-bladder, pleuritic, pyelitic inflammation, and suppurations) into the surgical wards.

It is, of course, impossible to keep staphylococci and streptococci out of the mouth, just as it is impossible to prevent occasional access of diphtheria, typhoid, pneumococcus, tubercle, and other infections. But that fact does not deter us from taking the most extensive sanitary and hygienic precautions to keep typhoid or tubercle infection out of the water or milk we drink or the air we breathe. I am satisfied that by suitable measures this far greater evil of oral sepsis could be largely prevented.

I submit, then, once more—as I did in the first communications (1900) and later papers (1903) bearing the title of "Oral Sepsis"—that in the interests of the many sufferers from the great group of medical affections which it produces this condition of oral sepsis, the chief channel of access of all pyogenic affections, is urgently deserving of increased notice and attention. Knowing as we do the pathogenic qualities of staphylococci and streptococci, we have not the slightest excuse for allowing the mouth, so easily accessible to local measures, to remain the chief seat of its open wounds and a veritable hotbed for their development and propagation; on the contrary, it is a severe reflection on our profession if we allow it.

Even if the teeth were not subject to a very marked septic infective process—that which we term caries and cario-necrosis—and always remained intact except in so far as they were affected by the septic infection in the gums and in the periosteum of the sockets, the infective processes in the gums constitute very important septic wounds and are a great source of sepsis to the body. As a matter of experience this is often the case. The teeth remain intact or at least free from obvious caries or cario-necrosis; but the gums and periosteum of the sockets are the seat of numerous septic wounds. These effects are shown by septic suppuration, by deposit of tartar, sometimes in great masses on the teeth, on the gum margin and beneath the gum margins, by the formation of pockets (septic ulceration of periodonteum—periostitis), absorption of bone, and loosening of the teeth in their sockets.

All these conditions are very obvious to the doctor if looked for and observed, and they are very septic and productive of some of the worst septic effects on the bodily health. But in many cases they need not be so obvious. For the septic infection may be confined almost exclusively to the periodonteum (periosteum) of the sockets, and be evidenced only by ulceration of that membrane, pocket formation, loosening of the teeth, suppuration—sometimes, however, by very slight suppuration.

It is in poor patients that these septic conditions are most common. They have had "no care" of their mouths—their fate is the relatively happier one of having their septic roots lying exposed in all their nakedness surrounded with tartar, overgrown it may be by foul, septic, fungating gums. This sepsis is relatively open and above board—it stares one in the face when it is looked for. At the worst it is covered by plates—which they have been told not to remove (!)—covering septic roots—which they have been told to keep (!), in order to prevent any falling in of the gums. The conditions in these cases, atrociously septic as they are, are comparatively easily dealt with, for they can be seen and recognised; and even if the patient refuses to have his roots removed much of the sepsis is superficial and can be got at and removed by careful daily swabbing with antiseptic lotions. And if this can be done regularly the patient may ultimately be induced to have the septic root removed.

But the problem presented by similar conditions in private patients is a much more difficult one. One of the worst cases of sepsis I have ever seen was brought me by a doctor who told me that the mouth had been "carefully seen to and was in good order." The patient was a tall, handsome man in the prime of life—a case of severest Addisonian, so-called "pernicious," Idiopathic Anæmia. His mouth was, indeed, clean to all outside appearance, for it was one mass of gold caps, bridges, crowns, fillings, false teeth, &c., so ingeniously built up that one could hardly tell what was false and what was real. To free that man from his sepsis in his state of health involved what was really equivalent to a major operation in surgery. The conditions of sepsis, necrosis, &c., revealed on removal of this golden architecture were perfectly appalling.

No one has probably had more reason than I have had to admire the sheer ingenuity and mechanical skill constantly displayed by the dental surgeon. And no one has had more reason to appreciate the ghastly tragedies of oral sepsis which his misplaced ingenuity so often carries in its train. Gold fillings, gold caps, gold bridges, gold crowns, fixed dentures, built in, on, and around diseased teeth, form a veritable mausoleum of gold over a mass of sepsis to which there is no parallel in the whole realm of medicine or surgery. The whole constitutes a perfect gold trap of sepsis of which the patient is proud and which no persuasion will induce him to part with. For has it not cost him much money, and has he not been proud to have his black roots elegantly covered with beaten gold, although no ingenuity in the world can incorporate the gold edge of the cap or crown with the underlying surfaces of the root beneath the edges of the gums? There is no rank of society free from the fatal effects on health of this surgical malpractice.

I speak from experience. The worst cases of anæmia, gastritis, colitis of all kinds and degrees, of obscure fever of unknown origin, or purpura, or nervous disturbances of all kinds ranging from mental depression up to actual lesions of the cord, of chronic rheumatic affections, of kidney disease are those which owe their origin to, or are gravely complicated by, the oral sepsis produced in private patients by these gold traps of sepsis. Time and again I have traced the very first onset of the whole trouble of which they complained to a period within a month or two of their insertion. The sepsis hereby produced is particularly severe and hurtful in its effects. For it is dammed up in the bone and in the periosteum, and cannot be got rid of by any antiseptic measures which the patient or the doctor can carry out. Moreover, it is painless, and its septic effects therefore go on steadily accumulating in intensity without drawing attention to their seat of origin.

Such are the fruits of this baneful so-called "conservative dentistry." The title would be a fitting one if the teeth were a series of ivory pegs planted in stone sockets. But the teeth being what they are—namely, highly developed pieces of bone tissue, possessing, I would point out, a richer blood- and nerve-supply than any piece of tissue of the same size in the whole body—and planted in sockets of bone with the closest vascular relations to the bone and the soft tissues of the periosteum and the gums, the title that would best describe the dentistry here referred to would be that of "septic dentistry." Conservative it is, but only in one sense. It conserves the sepsis which it produces by the gold work it places over and around the teeth, by the satisfaction which it gives the patient, by the pride which the dentist responsible for it feels in his "high-class American" work, and by his inability or unwillingness to recognise the septic effects which it produces.

After ten years' experience of the nature of these effects and of the difficulties encountered in removing them, I feel that the only solution of the difficulty may best be described in the terms employed by Huxley, modified to suit this particular case:—

> There can be no doubt that the future of Oral pathology and treatment, and therefore of practical dentistry, depends upon the extent to which those who occupy themselves with these subjects are trained in the principles and impregnated with the fundamental truths of Oral Sepsis and Oral Antisepsis.

The problem is an important one for the dental profession, and its solution is an important one in the interests of public health, especially of our school children, 30 to 50 per cent. of whom suffer from dental and oral sepsis and its tonsillitic, pharyngeal, glandular, and other effects. For while a large body of that profession are engaged in dealing successfully with the difficult problems of dental disease and of oral sepsis, another body is no less steadily engaged in promoting sepsis of the worst character and degree by ignoring the fundamental truths connected with the anatomy, physiology, and pathology of the tissues with which they deal. To gold-cap a healthy or diseased tooth in order to beautify or "preserve" (!) it is the negation of every one of these truths—a veritable apotheosis of septic surgery, and of surgical and medical malpractice.

The medical ill-effects of this septic surgery are to be seen every day in those who are the victims of this gilded dentistry—in their dirty-grey, sallow, pale, wax-like complexions, and in the chronic dyspepsias, intestinal disorders, ill-health, anæmias, and nervous ("neurotic") complaints from which they suffer. In no class of patients and in no country are these, in my observation, more common than among Americans and in America, the original home of this class of work.

### CLINICAL EFFECTS OF SEPSIS.

The chief feature of this particular oral sepsis is that the whole of it is swallowed or absorbed into the lymphatics and blood. Unlike the sepsis of open wounds on the outside of the body none of it is got rid of by free discharge on the surface. The effects of it, therefore, fall in the first place upon the whole of the alimentary tract from the tonsils downwards. These effects include every degree and variety of tonsillitis and pharyngitis; of gastric trouble from functional dyspepsia up to gastritis and gastric ulcer; and every degree and variety of enteritis and colitis, and troubles in adjacent parts—e.g., appendicitis. The effects fall in the second place upon the glands (adenitis); on the blood (septic anæmia, purpura, fever, septicæmia); on the joints (arthritis); on the kidneys (nephritis); and on the nervous system.

I cannot within the time at my disposal bring before you all the facts relating to medical sepsis or to its greatest cause—oral sepsis—on which these conclusions as to their importance are based. This I have already done in the series of papers already referred to. I propose rather to deal with you as you dealt with your assumed inquirer in the matter of antiseptic surgery—namely, enunciate briefly certain definite principles that may appeal to you, and illustrate these by a few recent cases selected at random.

The first of these principles is that the sepsis here had in view is all swallowed or absorbed, and that infection with staphylococcal and streptococcal organisms carries with it certain definite and deleterious effects wherever it is found. These effects vary, naturally, with the site of the infection and the degree of resistance offered by the tissues which are the seat of the invasion.

In the case of the mouth the mere presence of staphylococci and streptococci on the surface of the mucosa, or on the tongue, or in the mouth secretions, or in the saprophytic flora which abounds in the mouth, does not of itself cause disease, any more than their presence on the uninjured skin. But the matter is totally different when they become seated in open wounds in the edges of the gums adjacent to carious teeth; or extend from this, their first site, downwards along the periosteum (periodontal membrane) of the tooth socket. The infection is then no longer a superficial one—it is in connexion with the soft tissues, periosteum, and bone. The resistance of these tissues, especially the gums, is fortunately very great; hence a degree of infection which anywhere else in the body would certainly draw attention to itself by its redness, swelling, heat, and pain, may indeed cause redness and swelling, but does not necessarily cause any pain. This is the more to be regretted, for a feature of the septic infection in the gums, the teeth, or in the sockets of the teeth is that it is infection in contact with diseased bone, and its virulence is intensely aggravated by this fact. For no septic infection is more intensely virulent than that connected with diseased bone. I speak from personal experience on this point. The only two occasions in which I ran a very close risk—in one instance of my life, in the other of a limb or my life—were two in which in my post-mortem work I contracted a blood poisoning from pus arising in connexion with diseased bone. One of these was of a case of "septic anæmia," in which I pricked my finger while handling the tongue from a mouth full of oral sepsis. The symptoms showed themselves in 12 hours and were ushered in by faintness and rigors, fever of 103°–104°, and cellulitis of the whole arm before any local disturbance had shown itself.

Such untoward effects in the case of infection of the gums or jaws are very rare, although I have seen complete gangrenous necrosis of the whole of the alveolus and the bone of the hard palate, pyæmia and death result from this infection. But although such fulminating effects are exceptional, septic effects of various kinds and degrees are invariably present. These effects are not proportionate to the mere amount of the existing sepsis, but depend on its virulence. The most intense anæmia, blood poisoning, hectic fever, and even ulcerative endocarditis may in my experience be produced by one septic amalgam stopping, or by a small deep-seated alveolar abscess, or an unrecognised suppuration of the antrum or nasal sinuses. On the other hand, a man may have the foulest sepsis for years without apparently any ill-effect. But he need not vaunt himself unduly upon this comparative immunity; sooner or later his sepsis will find him out (Case 10). For even if it does not itself produce definite disease of its own, it will certainly complicate any independent disease from which he may afterwards suffer; and its effects, although unrecognised, may really constitute some of the most prominent features of his disease (Cases 7, 8, 9, and 10).

A patient's illness is not necessarily made up of the effects of his chief disease. The degree of ill-health or of the gastric, intestinal, febrile, anæmic, and nervous disturbances from which he suffers are by no means necessarily connected with, and due to, his chief disease. The chief interest of clinical medicine, as distinguished from systematic medicine, lies in the recognition of this great fact—in, so to speak, dissecting out all the causal factors operating in any individual case, and in removing so far as possible every

**adventitious factor, even if the chief one—e.g., permanent organic disease—is beyond control.**

CASES.

CASE 1. *Septic gastritis.*—A patient, a man aged 32, was admitted suffering from chronic indigestion and gastric trouble. His habits had been regular; his bodily physique good. There was no apparent reason why he of all men should be subject to gastric trouble. On examination I found he had a tooth plate in his upper jaw which he had not removed for two and a half years, which he was told not to remove, and which, even now, he could only remove with difficulty and after persuasion. On its removal there was found the most intense septic inflammation and ulceration of the gums around a number of necrosed roots underneath the plate. This was immediately dressed by me. After careful antiseptic dressing for several days to get rid of some of the septic infection, with immediate and obvious benefit to the patient, he ultimately consented to have the roots removed, and the patient left the hospital in a week or two entirely free from all gastric trouble. The condition was "septic gastritis" produced by an intense "oral sepsis," due to the insensate action of a dentist in supplying and fixing a plate to be worn over necrosed roots.

**Nine-tenths of the cases of dyspepsia and gastric trouble which I see are caused or complicated by similar oral sepsis, and respond at once to removal of this sepsis. Nevertheless the sepsis is overlooked because not looked for.**

CASE 2. *Septic gastritis.*—I was shown recently a very severe and obscure case of gastritis in a woman aged 33. She presented a dirty grey complexion and a broken-down appearance. The fullest report of her case was read to me, including the results of a chemical and microscopical examination of her stomach contents and of her fæces. On examination she presented the most intense oral sepsis—ulceration of the gums, with large deposits of tartar covering the ulcers and extending up to, and enclosing, the teeth, many of these being quite loose in their sockets. She had swallowed this infection for years, and it had caused not only "septic" gastritis, but also septic colitis, for, as was duly noted, pus was present in the fæces.

**Everything in connexion with the case had been duly observed and recorded, including the presence of pus in the fæces. But the condition of the mouth, although noted to be bad, had not been dealt with.**

CASE 3. "*Septic colitis.*"—A patient was admitted suffering from chronic colitis of many years' standing; he had been an in-patient of other hospitals for the same complaint. He passed large masses of mucus with each motion. The case was so-called "mucous colitis," a title which seems to mean something definite, but merely means that he has some kind of colitis, and that he is passing mucus. On examination I found he had some 20 rotten roots in his mouth, all of them necrosed down to the level of the gum. The infection had all been swallowed for many years. I termed the condition "septic colitis." The teeth were carefully dressed for several days and then extracted. Three or four days later the patient ceased to pass any more clumps of mucus in his stools, the bowels became regular, and in two or three weeks' time he went out free from all intestinal trouble. The condition was one of septic colitis caused by oral sepsis.

**Even if the colitis had been originally due to some other cause—e.g., dysentery, typhoid—it would have been intensely aggravated and complicated by this additional septic infection. I have seen many similar cases, and the connexion between oral sepsis and colitis is by no means sufficiently recognised.**

CASE 4. *Septic anæmia.*—A patient had suffered from anæmia for six or seven years. Five or six years ago the anæmia was so marked that she was warned by a distinguished surgeon who saw her that it might become "pernicious." When seen by me (1907) she was leading an invalid's life, suffering from chronic anæmia, weakness, giddiness, and palpitation, going about from place to place in search of health. Her history was the following. For the last twelve years she had had pains, very acute, of a neuralgic character over the right frontal region, and this was followed by a discharge of pus from the nose, followed by a similar attack the following winter. From time to time there was tenderness over the right frontal region with increase of discharge. She was sent to me by a well-known nose specialist with the following note: "She has a chronic, foul empyema of the right frontal sinus, and there is muco-pus in the corresponding antrum. Whether these conditions cause the anæmia I do not know; they do not help it getting better. My suggestion is that she should let you relieve her anæmia as far as possible, and when she is well enough she might have the sinus dealt with." My own opinion was quite definite. The whole history and the degree of blood-change—viz., 50 per cent. of hæmoglobin—satisfied me that the anæmia was "septic anæmia," and that it owed its origin to the suppuration of the frontal sinus. I therefore recommended that this latter should be dealt with at once. This was done, and the patient left the home in a few weeks' time entirely cured of her ill-health and anæmia, from which she had suffered for six or seven years.

CASE 5. *Septic anæmia.*—A patient, aged 64, sent to me on Sept. 8th for severe anæmia, from which he had suffered since February. Red corpuscles 41 per cent., hæmoglobin 40 per cent., leucocytes 5000. No history of loss of blood. I suspected septic anæmia and looked for possible causes. I found he had only five teeth markedly septic (oral sepsis 3°), with two small necrosed roots buried in the gum of the right upper alveolus, the gum margin and alveolus being much thickened. The right cheek was somewhat swollen and puffy, with some pain in the left side and tenderness of the last molar. On inquiry I learnt that at the beginning of the illness he had an aching tooth and went to a dentist who supplied him with a set of plates ill-fitting and uncomfortable, which had to be rejected; then supplied another set which also had to be rejected. (The dentist, it will be seen, failed to recognise the actual septic trouble presented by the remaining teeth.) The patient was placed in a home on Sept. 14th. On trans-illumination no antrum disease was discovered. I had the five teeth extracted with difficulty, owing to chronic osteitis. On Sept. 20th the corpuscles and hæmoglobin had risen to 49 and 58 per cent. respectively; and the patient left the home on Sept. 25th looking well, with 75 per cent. of corpuscles and 75 per cent. of hæmoglobin. By Oct. 18th he had 84 per cent. of hæmoglobin, and on Nov. 17th he had 91 per cent. of corpuscles and 94 per cent. of hæmoglobin, and was looking in good health.

CASE 6. *Septic anæmia.*—A man was admitted into a surgical ward on account of gastric symptoms with some hæmatemesis, suggestive of cancer. On examination nothing surgical was found justifying operation. But his anæmia was most profound, and he was transferred to my medical ward. On examination I considered the degree of anæmia to be too great to be accounted for by any loss of blood which he had, and there was marked fever. I therefore examined him for other causes. The gums were very pale and clean, and the teeth good with the exception of one upper bicuspid. Even on inspection I drew the attention of my class to its importance as a possible seat of hidden sepsis. On examining it a teaspoonful of pus burst from it. On further examination by transillumination the antrum above showed a deep shadow. The necrosed root was extracted and the antrum opened up and found full of the most offensively smelling pus. Between the time when he was first examined by me and the operation the pus discharged from the socket of the necrosed tooth was about two or three teaspoonfuls daily. He had swallowed and absorbed this daily—probably for many months—possibly years, with resulting gastritis and anæmia; and he was transferred from the surgical to the medical ward because his condition was essentially a medical one—not a surgical one (!). The condition was one of oral medical sepsis, unlooked for, unrecognised—due to the sepis produced by one septic root, which had probably "never given him any trouble."

CASE 7. *Septic anæmia as a complication of phthisis.*—A man suffering from advanced phthisis looked so exceptionally pale and anæmic that had he had no phthisical signs in the lung he might well have been considered a case of anæmia. His pallor and anæmia, however, were not connected with his phthisis, but with the extremist degree of oral sepsis which he also presented. His health greatly improved when the condition had been dealt with. His anæmia was largely the anæmia which I have termed "septic anæmia."

CASE 8. *Septic anæmia as a complication of chronic nephritis.*—A patient suffering from chronic nephritis may, and often does, present an extremely anæmic appearance, and in many cases a very severe degree of anæmia may be present in the blood. But that also is not necessarily a result of his nephritis, but may be, and often is, due to co-existing oral sepsis, sometimes of an extreme degree. So far from his anæmia being the result of his nephritis, the nephritis may be, and, in my experience and judgment, often is, largely a concurrent effect of the sepsis causing his anæmia.

CASE 9. *Septic anæmia complicating gastric ulcer and chlorosis.*—A girl is admitted suffering from the symptoms of gastric ulcer, and she may, and often does, present an extremely anæmic appearance. In her case the anæmia is promptly designated chlorosis, but it is not necessarily wholly of that character. For she may, and frequently does, present an extreme degree of oral sepsis. This sepsis is, in my observation, largely the cause not only of her anæmia but also of the gastric ulcer. Her trouble is by no means only gastric ulcer; both the gastric ulceration and her anæmia have originally been caused by the overlooked sepsis of her mouth. They are really septic in their nature, and if the temperature of cases of gastric ulcer be watched it will be found that a certain amount of fever is very often present. And a still more interesting practical result may be noted—viz., that on removal of the oral sepsis the whole conditions of gastric trouble, anæmia, and fever clear up together.

CASE 10. *As a complication of nephritis.*—A patient suffered from chronic Bright's disease, and presented all the usual symptoms and features of that condition—urinary changes, vascular changes, eye changes, œdema, headache, drowsiness, &c., including also a varying degree of fever. The temperature suddenly rose, and erysipelatous cellulitis of one side of the face appeared. The condition thus appeared clinically as one of chronic Bright's disease, complicated by erysipelas. On examination a deep ulcer with much stomatitis was found on the buccal mucous membrane of the affected cheek. The condition then appeared clinically to be kidney disease complicated by erysipelas and ulcerative stomatitis. On further examination the ulcer of the mouth was found to be directly in contact with an intensely septic molar root, and many other teeth showed marked septic gingivitis, with tartar deposit and pockets (septic periodontitis). These latter septic lesions had obviously been there for years. The ulcerative stomatitis and the erysipelas were not sequelæ of chronic kidney disease, but the direct manifestations of an entirely different disease—viz., septic infection which had probably existed for many years. The irregular fever presented by the case was also septic. We had thus two intercurrent conditions—kidney disease and sepsis. The latter is euphemistically termed a "terminal" infection—meaning thereby that it has come on towards the end of the patient's chief disease. But this infection was not "terminal"—was not determined by the kidney disease. It has existed for many years prior possibly to the nephritis, and the continuous excretion during these years of its toxins was quite capable of producing a chronic tubular nephritis; or, failing that, was certainly aggravating any nephritis due to other causes.

*As a Complication of Specific Fevers.*

**The following cases show to what extent oral sepsis complicates specific fevers, such as scarlet fever, typhoid, diphtheria, and the striking benefits to be got from its removal.**

**In 648 cases of scarlet fever admitted into the London Fever Hospital under my care in the four years 1904–07, the incidence of oral sepsis, carefully noted by myself, varied from 25 per cent. to 43 per cent. The effect of oral antisepsis—the removal, as far as possible, immediately on admission of every trace of oral sepsis around the patients' teeth and gums by daily swabbings with 1–40 carbolic acid solution—throughout the earlier part of the disease was very striking. The chief complications of the disease were reduced as follows: The incidence of secondary adenitis was reduced from 9·6 per cent. in 1904 to 3·3 per cent. in**

1906, and 1·8 in 1907; of cellulitis of the neck from 5·2 per cent. in 1904 to 2·8 in 1906, and *nil* in 1907; of glandular suppuration from 1·7 per cent. in 1904 to 0·5 in 1906, and *nil* in 1907. The striking improvement was due to the increasing care taken by myself and by my residents and nurses under my instructions. In only one or two cases out of the whole series were any teeth extracted.

### PRINCIPLES OF TREATMENT.

What are the general principles of the treatment applicable to medical sepsis? The first and most important is curiosity about and careful observation of the actual character and degree of the septic foci present in the mouth (naso-pharynx or elsewhere) in every case of medical disease. This observation cannot be made by a cursory glance into the mouth and a general conclusion to the effect that the "teeth are fairly good," or the mouth "fairly clean," or that the mouth "requires to be seen to." *If you look* closely into the mouth of your patients and note what you see *you will observe* every degree and variety of septic gingivitis; every degree and variety of septic ulceration; every degree of tartar deposit as a great effect of this septic inflammation and ulceration; every degree of suppurative inflammation of the gums; every degree and effect of septic periostitis and periodontitis with formation of pockets and loosening of teeth; every degree and effect of septic osteitis—e.g., rarefying osteitis, causing recession of the bone socket, or formative osteitis, causing thickening of alveolus; every degree and variety of septic caries and necrosis of the teeth; and as a result of all these conditions, singly or combined, every degree and variety of septic stomatitis, simple, ulcerative, gangrenous. You will see all this in infinitely less time than it takes to examine a specimen of the gastric contents, or of the fæces, or of the urine, or of the sputum; in far less time and with far less labour than it will take you to examine the nose, or the nasopharynx, or the larynx; in far less time than it takes you to examine the heart, or the liver, or, indeed, any other organ of the body. In particular cases you will observe that all these septic conditions are produced, or intensely aggravated, by toothplates covering necrosed roots, by amalgam and gold fillings which have become septic, by porcelain crowns with gold collars, by gold caps over diseased teeth, gold bridges and other gold fixed dentures which, however good to begin with, are never really aseptic, and are liable to become extremely septic. All these you can observe in a few minutes if you look for them—in less time almost than it takes to mention them.

The prime indication in treatment is thus to recognise the septic infective nature of these mouth lesions and their true relations to each other—to recognise which are the causes and which are the effects.

As I have shown, the course of the septic infection is from the gums to the periodonteum (periosteum) of the root, and thence to the bone of the socket. The results are septic gingivitis with ulceration, septic periodontitis (periostitis) with ulceration (pocket formation), rarefying osteitis of the tooth itself or of the socket with loosening of the tooth. *As a result* and accompaniment of the whole of these processes, we have the formation and deposition of tartar in larger or smaller amounts on the edges of the gums, in the pockets, or on the tooth itself. The prime causal factor in all these processes is the septic infection; all the other processes—gingivitis, periodontitis and periostitis, osteitis, and tartar deposits—are the results of this septic inflammation and ulceration.

I am accustomed to ascertain the degree of oral sepsis present in every case by close examination of the condition of the gum and bone around each tooth; and to indicate the degree of sepsis—whether slight, moderate, or severe—by the figures 1°, 2°, 3° respectively. In many cases these figures do not suffice; for the degree of sepsis is so great that it can only be expressed by figures up to 7° or 10°. The patient may have all his teeth good, excepting one or two; and yet these may present such a degree of septic gingivitis, or ulceration, tartar deposit, or necrosis, or there may be so much tartar deposit in connexion with one or more of all of his teeth, that the degree of sepsis is really severe—3°, 5°, or 7°. Or he may present a veritable mausoleum of gold work in his mouth in, on, and around his teeth, and be regarded as having his mouth "well cared for" and "thoroughly set in order," when, as a matter of fact, the degree of sepsis and necrosis covered and hidden by the gold is perfectly appalling (10°). I speak from experience. I have had many such cases, and they are the most trying and pitiable cases with which one has to deal, for they are produced by dentists. The worst cases of septic gastritis, enteritis, and colitis, of ill-health, anæmia, obscure septic fever, and other manifestations of medical sepsis, are in my experience those in which the greatest so-called "care," the greatest amount of "American skill" in the shape of gold work, has been bestowed on the mouth. For the patient refuses to have it touched. He has paid much for it and he has been told by his dentist that it represents the highest dental skill. As one of them put it to me, "For the life of him he could not see what connexion it had with his condition"!—in his case, one of continuous ill-health, gastric and intestinal trouble, and finally of anæmia, from which he had suffered for 20 years. His death shortly afterwards "saw" the connexion.

In observing the degree of sepsis in my hospital cases I am in the habit of dressing the septic wounds. The method I employ is to swab the edges of the gums and teeth with cotton-wool and 1 in 60 carbolic in order to clean off pus and to enable me to see the character and extent of the underlying wounds. The wounds are thereby dressed at the same time that they are being examined, and all the superficial sepsis is got rid of. This antiseptic dressing of the gums should be carried out daily so long as open wounds are present, by the nurse or by the patient himself; and it is astonishing how quickly the septic conditions of the gums are improved thereby, and how quickly the patient feels and shows by his appearance the benefit of this antisepsis.

Both the observation of the lesions and the treatment here described can be carried out in almost as short a time as they can be described. Pus is removed, pieces—sometimes masses—of soft tartar can be tilted off the edges of the gums, the foul bleeding wounds lying underneath them are exposed and simultaneously dressed. This treatment is applied irrespective of the presence or absence of deeper-seated sepsis—such as that connected with carious or necrosed teeth. For even if such are present, as they so often are, the removal of the superficial sepsis is a great boon to the patient, since if left it would be swallowed. Moreover, if the teeth have to be removed, the preliminary dressing frees the wounds around the necrosed teeth from much of their sepsis, and thus prevents the risks of further infection of the fresh wounds created by the removal of the tooth.

A further, and by no means the least important, advantage of the simple antiseptic measures here described is this: the patient himself learns for the first time that care of the teeth does not necessarily mean extraction of teeth; that, short of extraction, much can be done without any discomfort or pain to himself; moreover, that he himself can in many cases carry out the necessary antiseptic measures. Weak, nervous, highly strung patients, who at first absolutely refuse to allow anything to be done to their mouth, will, after a short experience of antiseptic dressing, of its freedom from pain, and of the benefits they experience from it, consent without demur to the removal of their carious roots. In one such case under my care, admitted very ill with a long-continued fever of unknown nature, the patient ultimately consented to have 10 or 12 necrosed roots removed, and went out quite well—a marvel to herself and to the doctor who sent her in thinking she had some obscure malignant or tuberculous disease. The temperature, which had ranged between 101° and 103° for many weeks, fell to normal on the day after the removal of the septic roots.

These are very simple principles of treatment for a condition that carries with it so many ill-effects—so it may be said. Yes, the principles are simple—they are *only* (!) those of observation and recognition and removal of the sepsis responsible for these effects. They are of the same simple character as those underlying the washings and scrubbings of his own hands and the skin of the patient which the surgeon carries out with such patience and ritualistic care. They have the same object—namely, the removal or prevention of any sepsis that can possibly introduce septic infection into the body. Like these measures, they are most effective when carried out by the doctor himself, not left to others. They differ from the antiseptic measures of the surgeon in one respect—they are not carried out amid the same impressive antiseptic surroundings. They therefore lack the impressiveness of the surgeon's antiseptic precautions both for the patient and the medical onlooker. But this is a fault that can, and will, I hope, in the near future

be remedied. For the evil of sepsis in the mouth is a very prevalent one and can never be adequately dealt with by driving every sufferer from it through the already overtaxed and overburdened hospitals of the dental profession. Even after it is dealt with antiseptically in the manner above described by the doctors and surgeons whose cases it complicates, there will always remain sufficient for the dental surgeon to undertake in his own sphere.

The surroundings which I would fain see provided in both general and dental hospitals and children's schools for carrying out these initial and all-important antiseptic dressings of the mouth would be special dressing-rooms free from all costly appliances of dental chairs and dental apparatus, and furnished simply with the simpler antiseptic furniture of a surgical dressing-room. If patients could learn that they could have their gums and teeth antiseptically dressed by a competent nurse without any pain or discomfort to themselves, the evil of oral sepsis could be greatly prevented or kept in check. For they would learn from this experience what they cannot learn now—namely, the antiseptic objects and the benefits of cleanliness of the mouth. As one hospital patient put it, "No one had ever told me before."

These principles of treatment are indeed simple; they are only those underlying the whole practice of antiseptic surgery—namely, removal of sepsis whenever it is causing ill-effects and can be got at. If they can be put into practice in the domain of medicine to prevent or get rid of some of the most prevalent diseases in medicine, as in my experience they can be, it is the duty of the medical profession as a whole and each member of it within his degree to help to carry them into practice and to devise the necessary measures in their hospitals to enable them to be carried out.

The evil is so common and widespread that it is impossible to deal adequately with it—so it may be said. The same plea might have been urged in connexion with every other great practical advance in preventive medicine—e.g., the sanitary measures for the prevention of typhoid and other water-borne diseases. To deal effectively with such diseases—to teach people how to be clean in their sanitary arrangements—must have appeared an almost hopeless task when sanitary science was first put into practice. But everything can be done in time—if the principles underlying our efforts are sound.

So with this great evil of oral sepsis and its manifold ill-effects, far more widespread in their extent and no less severe in their character than those connected with typhoid or even with tuberculosis. The plea of helplessness to deal with it, I submit now as I did in my first papers on the subject, is a singularly poor one to be put forward or given any support to by the medical or surgical profession, at whose instigation the most elaborate and expensive equipments of hospitals have been, and are daily being, carried out.

# SUBTOTAL HYSTERECTOMY FOR FIBROMYOMA UTERI: FORTY ADDITIONAL HISTORIES.[1]

BY ALBAN H. G. DORAN, F.R.C.S. ENG.,
CONSULTING SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, MARYLEBONE-ROAD, N.W.

IN September, 1905, I read at a meeting of the Obstetrical Society of London a communication bearing the title "Subtotal Hysterectomy: After Histories of Sixty Cases."[2] I had already discovered that long series of "successful cases" of hysterectomy for fibroid tumours, when "success" simply means recovery from operation, teach little or are actually misleading, for "recovery" is by no means synonymous with cure. The tumour is gone, but certain discomforts may for a while embarrass the patient, and the surgeon should be aware of the nature of these possible discomforts. On that account I prepared tables of 60 cases in my own practice where the patient had not reached the menopause and where an after-history of at least two years was obtainable, tables drawn up after Dr. G. Crewdson Thomas's method. When one or both ovaries are saved a two years' history is absolutely needed, for as I then noted and as the present record of further experience will show, a kind of period may be observed for many months after a subtotal hysterectomy where both ovaries have been removed. Therefore I then rejected, as I now reject, many interesting cases where the after-histories were too short or otherwise imperfect. The main object of my memoir was to determine how far patients receive lasting benefit from subtotal hysterectomy, how far they are liable to certain discomforts, how far the preservation of more or less ovarian tissue may save them from these discomforts, and lastly, how far it may be necessary to preserve some of the endometrium, or, in surgical language, how far it is advisable to amputate the fibroid uterus above the level of the os internum.

In this communication I analyse 40 similar cases from my own operative practice as before. The operations in the new series were performed between February, 1903, and February, 1908. Thus I have collected 100 cases, which simplifies, among other things, the calculation of percentages, whilst the value of the two series is in other respects greatly enhanced by their combination. I earnestly hope that operators who prefer panhysterectomy in the treatment of uterine fibroid will see their way to publish similar analyses of their operative practice. I do not deny that the complete operation has its advantages. I will not discuss either the immediate or distant benefits or risks associated with the preservation of the cervix, for the aim of this communication is not the consideration of the purely surgical merits of a certain operation, but the making known of its remote effects on the patient. I exclude all other considerations, many of high importance, such as the value of the cervix as a support to the pelvic floor.[3] On the other hand, I must be excused for avoiding all purely physiological questions, and therefore I will not discuss the important monographs of Scott Carmichael and Marshall,[4] Blair Bell and Hick,[5] Bond,[6] and the British and foreign workers who have recently experimented on transplantation.[7] We must study with care the reports issued by these distinguished authorities; and for my own part I follow their example when I publish the result of my own experience. With all respect to them I must turn attention to the truth that women are not rabbits. When we remember how many fallacies have arisen through theorizing on the homologies of bones, how can we rely on theories about the homologies of the ovary and endometrium in woman and in the lower mammals? We must not take for granted any assumption that lutein is the same in *Lepus* as in *Homo* and that the endometrium immediately above the cervix bears the same relation to the ovary in the rabbit as in our own species. At the same time, we know that the able, painstaking, and experienced workers to whom I have just referred will do their best to throw more light on these dark questions.

Dr. Arthur E. Giles, in an important statistical treatise on his operative work,[8] finds that "after hysterectomy menstruation usually ceases; but if a small portion of the body of the uterus be left, as may happen in a high supravaginal amputation, menstruation may continue regularly for a longer or shorter period, with no other apparent difference than a diminution in quantity." His experience agrees with my own, but his tables are not drawn up quite after the plan which Crewdson Thomas and myself have adopted, as many after-histories are too short for the present purpose, and cases of panhysterectomy and amputations for fibrosis as well as fibro-myomatous tumour are included. Still, although a precise scrutiny of the level of amputation would have been desirable, we must admit that Dr. Giles

has taken great pains in his analyses of menopause symptoms after subtotal hysterectomy. Mrs. Scharlieb has published two instructive series of tables of operations for fibromyomata of the uterus,[9] but not quite on the same plan as my own. We hope to hear more about after-histories from so competent an authority.

Lastly, in respect to statistical tables designed to throw more light on the questions under consideration, the section would, I am sure, be much interested if certain strong advocates of panhysterectomy,[10] well known and honoured by us all, would furnish us with analytical tables such as I have prepared.

In regard to the recently expressed opinions of others in respect to the saving of ovarian tissue and the preservation of a piece of endometrium by amputation above the os internum, I find that some writers are in accord with views expressed in this communication. Kelly and Cullen[11] declare, on statistical evidence which they publish, that the surgeon should, wherever possible, save every normal ovary. In their series of 56 cases where one or both ovaries were saved the after-histories are shorter than two years in at least the last two cases, a fact which might draw down criticism from those who make light of conservative methods. In order to exclude absolutely any abnormally early appearance of the menopause these writers only include in their table cases in which the patients were not over 41 years of age. I have included in my series all patients who still menstruated, as the sudden arrest of the catamenial function is to be avoided if possible at any age, and if a relatively aged woman in whom that function persists is subjected to operation it is both interesting and important to ascertain the after-history.

Dr. Howard Kelly, however, writing independently, advocates preservation of a piece of endometrium, as well as one or both ovaries.[12] "I have in selected cases proceeded upon the plan of keeping a portion of the uterine body with the mucosa above the cervix in women who were still menstruating, in this way succeeding in preserving regular menstruation in many cases of non-malignant disease, for the most part treated to-day by a cervical amputation of the uterus or even by panhysterectomy. The two classes of patients best fitted for this plan of treatment are, on the one hand, those with fibroid uteri not suitable for myomectomy, nor demanding panhysterectomy, and, on the other, the large group of subinvoluted hæmorrhagic uteri. It is a *sine quâ non* in each case that one or both ovaries must be sound enough to be retained. It is sufficient to retain a little pocket of the mucosa within the uterus big enough to lodge the end of the little finger, while more should be kept if possible; with the mucosa the corresponding portion of the muscular investiture is retained. The tissues so conserved are then sutured face to face as not seriously to interfere with the blood-supply. An amputation of this sort is easily done by simply cutting through the uterine wall well above the cervix, starting, in other words, to make a high amputation in and not below the uterine body."

Thus, like Abel, Zweifel, and myself, Howard Kelly deliberately saves some of the endometrium when possible in order to prevent as far as practicable a sudden cessation of the menopause. He is yet more conservative than other operators, for he "grades the amputations done *in utero* from one which is barely made supracervical to one which is done at the very fundus itself and is principally a myomectomy." He practises a horizontal and a vertical amputation, describing the steps of each operation. He publishes nine results, but no doubt a longer series will some day be issued.

These tables certainly show that there can be no doubt that the preservation of ovarian tissue is advisable, provided that the ovaries are healthy and that their sacrifice is not demanded for certain surgical reasons. The preservation of a piece of endometrium seems almost equally advisable. The saved fragment may, it will be seen, carry on menstrual functions when both the ovaries are sacrificed. The advantages of sparing a piece of the uterine mucosa comes out clearly in Group II., where one ovary was spared. The point is obscured in Group III., where both ovaries were saved, owing to certain non-essential complications present in no less than three cases.

GROUP I.

*Both ovaries removed.*—Twelve cases come under this heading—namely, Cases 61, 64, 69, 73, 77, 78, 81, 84, 90, 93, 96, and 99.

*Age.*—Five between 35 and 40 years (Cases 61, 78, 84, 96, and 99); from 40 to 45 years, five (Cases 64, 73, 77, 81, and 90); from 45 to 50 years, one (No. 69); and one 50 years old (Case 93).

*Married or single.*—Ten married (Cases 61, 64, 69, 73, 78, 84, 90, 93, 96, and 99); and two single (Cases 77 and 81).

*Results.*—1. Menopause neither immediate nor complete: 1 (Case 64). 2. Menopause complete, no symptoms: 3 (Cases 69, 93, and 96). 3. Menopause complete, distinct but mild symptoms: 4 (Cases 61, 73, 78, and 81). 4. Menopause complete, severe symptoms: 4 (Cases 77, 84, 90, and 99).

*Analysis of the case where the menopause was neither immediate nor complete.*—No. 64. Age 44. Married. Four pregnancies, last 12 years. Hæmorrhages: Severe menorrhagia. Size of tumour: Small; it involved the cervix. Line of amputation: Above os internum. Ovaries: Normal. No. 64 may be ranked among those interesting cases where, although both ovaries were removed, it is certain that some of the endometrium was saved and where the periods continued for two years, whilst no flushings or other distressing symptoms preceded or followed their cessation. Last August, close upon seven years after the operation, the patient wrote to inform me that she had grown stout and had never felt so well since her youth, a "history," however, quite common after the menopause. This patient had been under treatment for uterine hæmorrhages, beginning after her last confinement 11 years previously. Recently they had been very severe; one attack two months before the operation lasted five weeks and nearly proved fatal. There was double aortic disease distinct but not pronounced, and small external hæmorrhoids. I enucleated a fibromyoma of the size of a Tangerine orange, which mostly grew in the anterior wall of the supravaginal portion of the cervix. The body of the uterus was very bulky, hæmostasis was difficult, and on that account I did not attempt to finish the operation as a pure myomectomy, whilst the appendages had to be sacrificed in order to secure the ovarian vessels far above the engorged veins on the uterus. The artery of each round ligament required separate ligature. Then the uterus became pale and diminished in bulk. I thought that some endometrium might well be saved, bearing in mind some previous cases, so I amputated above the os internum. The anterior wall of the cervix made a good flap, after careful trimming, over a stump which was not at all bulky.

*Relation to cases in the old tables.*—This case (Case 64) resembles Case 36 in the old tables, where menorrhagia was marked. The periods reappeared three months after the operation, and continued regular for seven months; by the end of two years there was only occasional show. There were no flushings. In Case 64 the periods were regular. In Case 12 the periods, though irregular, persisted for over two years, but there were flushings, which subsided when the periods ceased. In Case 29, not only were both ovaries removed but the line of amputation passed below the os internum. A slight mucous discharge persisted and it was distinctly coloured every four weeks. Possibly, as I suggested when I reported the case, there were endometritic elements in the cervical mucosa. We see clearly, however, that in 10 per cent. in this group and in 4 per cent. of the whole series menstruation continued for some time after the removal of both ovaries, though the influence of the other factor under consideration is not evident. They seem to prove that the endometrium can maintain the catamenial functions when the ovaries have been extirpated.

*Analysis of the three cases where the menopause was complete without symptoms.*—Age: The youngest (Case 96) was 38 years old; the eldest (Case 93) was 50. Case 69 was 48.

[9] See "An Analysis of a Second Hundred Cases of Operation for Fibro-myomata Uteri, with Special Reference to their Degenerations and Local Complications." Proceedings of the Royal Society of Medicine, vol. ii., Obstetric and Gynæcological Section, p. 45.

[10] See J. D. Malcolm "On the Advisability of Removing the Cervix in Performing Hysterectomy for Fibro-myomatous Uterine Tumours," Transactions of the Obstetrical Society, vol. xlix., 1907, p. 148. An instructive discussion followed the reading of this important communication, and is published in full. Salva Mercadé (La Période post opératoire, soins et accidents, 1910, pp. 450–2) shows that the chances of cancerous degeneration of the stump have been greatly overestimated owing to certain sources of fallacy.

[11] Myoma of the Uterus, 1901, p. 603.

[12] "Amputation of the Uterus in the Corpus to Preserve the Menstrual Function," American Journal of Obstetrics, April, 1909, p. 570.

Married or single: All three married. Hæmorrhages: Only in Case 96, where a submucous growth had developed. Size of tumour: 3½ lb. in Case 69; moderate-sized, mesosalpinx invaded, mesenteric adhesion in Case 93. Small in Case 96. Line of amputation: Above os internum in 1 case (Case 93); below in 2 (Cases 69 and 96). Ovaries: Associated with tubal disease in 1 (Case 69), and normal in 2 (Cases 93 and 96). In Case 93, reported in THE LANCET of Nov. 9th, 1907, p. 1309, I operated on account of symptoms of chronic obstruction due to an adhesion of one lobe of the tumour to the mesentery. This adhesion formed an arch under which coils of small intestine became incarcerated. Although the patient was 50 years of age the periods were still present with more free show than when she was in the prime of life; such is not rarely the case in fibroid disease. For surgical reasons it seemed best to sacrifice the ovaries, but the uterus was amputated a little above the os internum; the stump was not fleshy and was easily covered over by a small flap. The menopause was complete and there were no flushings or any other symptoms. This satisfactory after-history is not always to be reported when both ovaries are removed from a relatively elderly woman who has not reached the menopause.

*Relation to cases in the old tables.*—Six came under this group (Cases 1, 6, 31, 37, 41, and 47). In 5 the line of amputation passed below the os internum; adding Cases 69 and 96, the total will be 7; in Case 41 this factor was uncertain. Adding Case 93, the total number of cases where the menopause was complete without symptoms, after removal of both ovaries, will be 9; that is, 22·5 per cent. in this group and 9 per cent. in the whole series.

*Analysis of the four cases where the menopause was complete with distinct but mild symptoms.*—Age: 2 under 40—Case 78 (36) and Case 61 (37); 2 under 45—Case 73 (43) and Case 81 (44). Married or single: 3 married (Cases 61, 73, and 78) and 1 single (Case 81). Hæmorrhages: Severe in 1 case (Case 61); moderate in 2 cases (Cases 78 and 81); and absent in 1 (Case 73). Size of the tumour: 11½ lb. in Case 61; 7 lb. 2 oz. in Case 81; 2½ lb. in Case 73; and 2½ lb.—"cystic perithelioma"—in Case 78. Line of amputation: Above os internum in 3 (Cases 61, 78, and 81) and below in 1 (Case 73). Condition of ovaries removed: Suspicious in appearance in 1 (Case 78); normal but drawn very high up in 2 (Cases 61 and 73). Lastly, in 81 "there was a true corpus luteum hæmatoma appearing as a blood cyst of the left ovary. The opposite (right) ovary has ovarian tissue extending into the ovarian ligament to within a quarter of an inch of the uterine cornu. The ovarian stroma has here produced a corpus luteum of most perfect type containing quite a large amount of compact lutein tissue" (C. Lockyer). Menopause symptoms in these cases: Limited in all four cases to occasional flushings.

The most noteworthy case in this group is Case 61. The patient was relatively young, 37 years of age, and had been married 14 years; she had borne six children, the youngest being three years old. A large bleeding uterine fibroid developed, there were strong omental adhesions, and a hæmatoma appearing as a solid body of the size of a chestnut lay in the omentum immediately above the line of adhesion; it represented an old hæmorrhage, no doubt due to the omentum being knocked backwards against the fibroid. The uterine appendages were very high up, and as the tumour was extremely vascular I found it necessary to tie the ovarian vessels on both sides; the vermiform appendix lay on the capsule on the right side, the broad ligaments were widely opened up, and the base of the tumour was enucleated from their folds. I was able to amputate the uterus immediately above the os internum, leaving a piece of healthy endometrium, whilst the muscular coat was cut thin. It may be noted that although a large vascular tumour, causing severe menorrhagia, was removed, the operation being lengthy on account of adhesions, enlarged vessels and enucleation, and the ovaries being sacrificed, nevertheless the sudden artificial menopause was not associated with severe symptoms in this case where endometrium was designedly saved.

*Relation to cases in the old tables.*—Nine came under this group—namely, Cases 2, 4, 5, 13, 16, 23, 28, 33, and 38. In all the nine mild flushings were noted, Case 23 had tinnitus, and Case 33 vertigo as well. In 4 cases the line of amputation passed below the os internum. Adding Case 73 in the present series the percentage will be 5. In 5 cases the line passed above the os internum. Adding Cases 61, 78, and 81, the percentage will be 8. The gross percentage of cases in this group where the menopause was complete, with distinct but mild symptoms, is 32·5, or 13 per cent. of the whole series.

*Analysis of the four cases where the menopause was complete, with severe symptoms.*—Age: Two between 35 and 40 (Cases 84 and 99) and two between 40 and 45 (Cases 77 and 90). Married or single: Three married (Cases 84, 90, and 99) and one single (Case 77). Hæmorrhages: None in three (Cases 84, 90, and 99) and distinct menorrhagia in one (Case 77). Size of tumour: In none was the tumour large; the operation was undertaken on account of pressure symptoms, &c.; in Case 77 there was also a fibroid in the left broad ligament, and in Case 90 the cervix was involved. Line of amputation: Above os internum in two (Cases 77 and 99) and below in two (Cases 84 and 90). Condition of ovaries removed: In the worst case (Case 77) the appendages were unavoidably damaged during the operation; in Case 90 both ovaries were cystic; in Cases 84 and 99 I found it advisable, for surgical reasons, to remove the ovaries. Menopause symptoms in these cases: Case 77 was the worst in the whole series, as the patient became insane, but it is by no means clear that this mental disease was due to the operation. The patient was aged 42 years, and subject to severe pelvic pains for two years, which kept her from her work; when under Dr. Cuthbert Lockyer's observation for five months she suffered from menorrhagia. Proptosis and tachycardia had been noted by a former medical attendant, but although the eyes were very prominent the pulse on admission was 84. There was no thyroid enlargement as in Case 74. The uterus was enlarged by a fibroid in its anterior wall and pushed to the right by a solid oval body as big as a turkey's egg. I removed the uterus and ovaries in June, 1905, enucleating the fibroid in the left broad ligament. The stump was fleshy and I trimmed it freely. This patient was a rheumatic subject. A little show was observed four times after the operation, but it is doubtful if it were menstrual. She returned to her professional duties and enjoyed very good health until November, 1908, over three years after the operation, when her health broke down. She suffered from constant flushings, worse by day; the last show was then observed. Tinnitus and deafness on the right side developed after November, and disease of the middle ear was detected; the flushings continued through 1909, but grew less severe. The patient complained of vertical headache and a "pumping noise." In the winter 1909–10 she improved greatly, but she rather suddenly became insane in the spring of 1910. Summoned home on account of her mother's illness, she arrived too late, finding her parent dead. This caused severe shock, and she then had an attack of influenza. On June 1st, 1910, the medical superintendent of the Berkshire Asylum reported that she was "very lost and rambling, and has periods of excitement." She was afterwards removed to Hanwell. Her sister had been twice under restraint. In the remaining cases (Cases 84, 90, and 99) the symptoms were nothing worse than severe flushings, generally with perspiration.

*Relation to cases in the old tables.*—Ten cases came under this important group—namely, Cases 3, 10, 14, 25, 26, 30, 35, 42, 44, and 54. In 8 the symptoms were, as in the present group, simply severe flushings, but Cases 25 and 26 were graver cases. The second, Case 26, was already intemperate before the operation; for three years after it the patient was troubled with flushings, which then ceased, and at the same time she resumed her intemperate habits and died from carbolic acid poisoning (suicidal?) at the end of six months. Case 25 resembled Case 77 in one respect, but the patient had already been under restraint before the operation, although I was not informed of the fact until afterwards. About five months after the operation she was troubled with persecutory delusions, which occasionally recurred for a year or two. This patient, 41 years of age, did not suffer from flushings. In 6 cases in the old tables amputation was made below the os internum: adding 84 and 90, the total will be 8. In the remaining 4 there was uncertainty about the level. The gross percentage of cases in this group, where the menopause was complete with severe symptoms, is 35, or 14 per cent. in the whole series. It will be seen that the percentage is much lower in the second and third groups, where the patient was not deprived of all ovarian tissue.

### GROUP II.

*One ovary saved.*—Thirteen cases come under this heading—namely, Cases 62, 63, 66, 72, 74, 76, 79, 80, 88, 39, 95, 98, and 100. Age: One 28 years old (Case 100); three between 35 and 40 (Cases 76, 80, and 98); six between 40 and 45 (Cases 63, 66, 74, 79, 89, and 95); and three between 45 and 50 (Cases 62, 72, and 88). Married or single: Five married (Cases 62, 66, 72, 95, and 98), and eight single (Cases 63, 74, 76, 79, 80, 88, 89, and 100).

*Results.*—1. Menopause neither immediate nor complete: 8 (Cases 62, 63, 66, 72, 79, 80, 89, and 89). 2. Menopause complete, no symptoms: 4 (Cases 74, 76, 95, and 100). 3. Menopause complete, distinct, but mild: 1 (Case 88).

*Analysis of the eight cases where the menopause was neither immediate nor complete.*—Age: Two between 35 and 40 (Cases 80 and 98), four between 40 and 45 (Case 63, 66, 79, and 89), and two between 45 and 50 (Cases 62 and 72). Married or single: Four married (Cases 62, 66, 72, and 98) and four single (Cases 63, 79, 80, and 89). Hæmorrhages: Severe and very chronic, Case 62; moderate menorrhagia associated with adenomatous polypus, Case 80; menorrhagia, Cases 63, 72, and 89; none in Cases 66, 79, and 98. Size of tumour: Very large in Case 66 (15 lb., peritheliomatous elements); large in Cases 63, 79, and 98; moderate in Cases 62 and 80; small in Cases 72 and 89. Line of amputation: Above the os internum in six (Cases 66, 72, 79, 80, 89, and 98) and below in two (Cases 62 and 63). Condition of ovary removed: In one case (Case 89) the left ovary was cystic and the cyst contained a hæmatolith, a perfectly flat triangular body, with a base three-quarters of an inch long. There had been much menorrhagia in this case, but neither pain nor ovarian tenderness. In the 7 remaining cases (Cases 62, 63, 66, 72, 79, 80, and 98) one ovary was sacrificed either to facilitate hæmostasis or because the corresponding broad ligament was opened up and damaged. Menopause symptoms in these cases: In Case 63, where the line of amputation was below the os internum, there were distinct flushings for several years. It is not quite certain that this case should come under this group, but I include it with the remaining seven because the patient declared that the show seen six months and also two years and two months after the operation was in both instances associated with molimen, and the flushings were in a certain measure periodical. In Case 62, where the line of amputation was also below the os internum, distinct show was seen three or four times after the operation, and for as long as six years at least there were occasional flushings with vertigo. The patient at the date of operation was still menstruating regularly, although 49 years old. In all the remaining 6 cases some endometrium was left behind. In Cases 66, 80, and 89 the period continued regular for several years. In Case 66, where the operation described elsewhere was very severe, the period continued for three years and then ceased; I saw the patient two years after the menopause, there had been no neuroses of any kind. In Case 80 the periods were quite regular, although scanty, four years after the operation; there had been no flushings. In Case 89 the condition was precisely similar three years after the operation. In Cases 72 and 98 the periods continued for a few months and there were flushings rather severe, and in Case 98 associated with headache. In Case 79 the periods remained quite regular for one year, and then the menopause came on slowly without any disagreeable symptoms.

*Relation to cases in the old tables.*—As in the new tables, eight cases came under this group, Cases 19, 34, 39, 43, 51, 52, 57, and 60. In all there was persistence of menstruation for a distinct period as in Cases 66, 80, and 89. Case 51 was remarkable, as the periods were regular for 16 months, then the show never reappeared, but a regular periodical molimen continued for at least a year and a half. In seven cases in the old tables the line of amputation was above the os internum, making with the six in the new tables a total of 13 per cent. In the remaining case there was some uncertainty about the level of amputation. The gross percentage of cases under this group is 16. However, another group collected from the old tables has been suppressed as not strictly necessary: I mean instances where the catamenia appeared after operation but were irregular, 5 in all.[13] Such cases are here included under "menopause neither immediate nor complete." In all 5 the line of amputation was above the os internum, making a total of 18 per cent. The gross percentage of cases where one ovary was saved and the menopause was neither immediate nor complete, the periods continuing either regular or irregular, amounts to 53·8 in this group, and 21 in the entire series. I may add that in one of the 5[14] added to the group as at present arranged, the same phenomenon was noted, such as I observed in Case 51. The periods were regular for some time after operation,[15] then the show of blood ceased, but for at least two years after its cessation the menstrual molimen recurred with perfect regularity. In Case 81, belonging to Group III., there was a similar but shorter persistence of molimen.

*Analysis of the four cases where the menopause was complete without symptoms.*—Age: One between 25 and 30 (Case 100), one between 35 and 40 (Case 76), and two between 40 and 45 (Cases 74 and 95—both 41). Married or single: One married (Case 95), and three single (Cases 74, 76, and 100). Hæmorrhages: Severe in one case (Case 76), and slight (distinct menorrhagia) in three cases (Cases 74, 95, and 100). Size of tumour: Very bulky, not weighed in one case (Case 76), 6 lb. in Case 74, 3 lb. 2 oz. in Case 95, and 1 lb. 2 oz. in Case 100. Line of amputation: Above the os internum in all four cases. Menopause symptoms: Flushings and headaches did not trouble any of the four cases. In Case 76 there was, four years after the operation, occasional tympanitic distension of the abdomen, probably due to dyspepsia. Case 74 deserves some notice. The patient was a single woman aged 41 years. She had been in weak health all her life, and latterly very subject to tonsillitis, for which she placed herself under the care of Dr. A. C. Tucker of Barnsbury. She admitted to him that she had frequent attacks of tremors with profuse perspiration ever since she was 20, after he had noted that there was marked exophthalmos with distinct enlargement of the thyroid body; the pulse was also unaccountably rapid. For nearly two years this patient was kept under appropriate treatment for the exophthalmos. At the same time abdominal swelling was observed; it developed into a well-defined tumour which extended for two inches above the umbilicus. The late Mr. Nunn advised operation. When the patient was admitted into the Samaritan Hospital in October, 1904, I found the exophthalmos marked, without nystagmus or defective sight. There were muscular tremors, and the pulse, even when the patient was kept quiet in bed, ranged from 132 to 140. Dr. C. Hubert Roberts examined her with me. Graefe and Stellwag's signs were absent; the thyroid body showed slight enlargement of the lateral lobes. The temperature never rose above 99° F. before operation. The patient's appetite was good; the tongue was rather glossy along the edges. I amputated the uterus above the cervix; the whole mass, which weighed 6 lb., consisted chiefly of a large interstitial fibroid; the left appendages were drawn up very high on the surface of the tumour and rotated to the right of the middle line. I was determined to save one ovary if possible owing to the patient's general condition, and was therefore well satisfied to find that the right ovary lay low down, quite outside the mass. In amputating the cervix I enucleated a large fibroid growth which had developed in the posterior wall of the uterus below the bigger fibroid and invaded the wall of the cervix. After the enucleation I passed the knife above the level of the os internum. Five years later the patient wrote to me saying that she had enjoyed good health ever since the operation, the periods had never returned, but no neuroses of any kind had developed. Dr. Tucker had recently detected renewed enlargement of the thyroid body and administered fresh thyroid tablets for two months, the enlargement steadily subsiding. The question of the relation of exophthalmos to the functions of the generative organs has recently been discussed by Pinard.[16] Condition of ovary removed: Normal in all four cases; sacrificed for surgical reasons.

*Analysis of the case where the menopause was complete with distinct but mild symptoms.*—Case 88. Age between 45 and 50. Single. Hæmorrhages: None, no menorrhagia. Size of

[13] Cases 17, 20, 24, 27, and 58. Case 20 was an instance where the periods continued for four years and perhaps longer, but there was amenorrhœa for six months in the second year. In Case 24 alone were flushings noted.

[14] Case 58.

[15] Not over six months; in Case 51 they continued for 16 months.

[16] "De l'Expression Symptomatique appelée Goitre Exophthalmique dans ses Rapports avec la Fonction de Reproduction chez la Femme," Annales de Gynécologie et d'Obstétrique, May, 1909, p. 257.

tumour: 2 lb. 5 oz., with a cyst in the left mesometrium (below ovary). Line of amputation: Above the os internum. Condition of ovary removed: Normal, but closely connected with the cyst in the mesometrium.

*Menopause symptoms.*—In Case 88 flushings and perspirations appeared in the third year, although there had not been a trace of show since the operation. They seemed to be associated with physical fatigue. On the other hand, the patient gained a stone in weight within three years, yet she had spit blood 15 years before the operation, and there were pulmonary complications during the first week after the removal of the uterus. It is not certain that the symptoms above noted were really due to suppression of the menstrual function.

*Severe menopause symptoms.*—Let it be remembered that in this subseries where one ovary was saved and the amputation carried above the os internum in 11 (all but 2 out of the 13) there was no instance of severe symptoms clearly attributable to the menopause.

*Relation to cases in the old tables.*—Once more I must explain that I have rearranged the groups of the "one ovary saved" series. In the older communication I included under one group all the cases where the menopause was complete and immediate after operation independently of menopause symptoms. The total was 15,[17] against 5 in the present group, Case 88 being added to Cases 74, 76, 95, and 100. In 8 of the old cases the line of amputation was above the os internum, as it was in all 5 of the new cases, making a total of 13 per cent. In 5 of the old cases the line was below. The total percentage of cases where the menopause was immediate and complete is 46·1 in this group and 18 in the entire series. Lastly, whilst in the group "both ovaries removed" in no less than 14 per cent. of the series, or 35 per cent. of that group, the menopause was complete with severe symptoms, in this "one ovary saved" series the percentage is 0, unless we consider that Cases 22, 32, 45, and 48 where sharp flushings occurred should be included under severe cases.

### GROUP III.

*Both ovaries saved.*—Fifteen cases come under this heading—namely, Cases 65, 67, 68, 70, 71, 75, 82, 83, 85, 86, 87, 91, 92, 94, and 97. Age: One between 25 and 30 (Case 67), one between 30 and 35 (Case 71), three between 35 and 49 (Cases 65, 86, and 97), four between 40 and 45 (Cases 68, 70, 85, and 94), four between 45 and 50 (Cases 82, 83, 87, and 91), and two over 50 (Cases 75 and 92). Married or single: Eight married (Cases 68, 70, 71, 75, 82, 83, 86, and 91) and seven single (Cases 65, 67, 85, 87, 92, 94, and 97).

*Results.*—1. Catamenia regular after operation: 5 cases (Cases 67, 71, 85, 86, and 97). 2. Catamenia soon suppressed: 2 cases (Cases 68 and 91). 3. Menopause complete and immediate after operation: 8 cases (Cases 65, 70, 75, 82, 83, 87, 92, and 94).

*Analysis of the five cases where the catamenia were regular after operation.*—Age: One between 25 and 30 (Case 67), one between 30 and 35 (Case 71), two between 35 and 40 (Cases 86 and 97), and one between 40 and 45 (Case 85). Married or single: Two married (Cases 71 and 86) and three single (Cases 67, 85, and 97). Hæmorrhages: Severe in Cases 71 and 85; moderate in Case 86; none in Cases 67 and 97. Size of tumour: Bulky, reaching nearly to the umbilicus, Cases 71 and 97; weight 2 lb., Case 67; 1 lb. 2 oz., Case 86; 1 lb. 1 oz. (bleeding), Case 85. Line of amputation: Above the os internum in all five cases.

*Catamenial history after operation.*—In no less than four cases the periods were still regular according to the last report in Cases 71, 85, 86, and 97; that is to say, they continued for at least five years in Case 71, for at least three years in Cases 85 and 86, and for at least two years and one month in Case 97. In one case they continued regular for well over one year and then became irregular, but had ceased before the date of the last report; this was Case 67. The last period was observed about four years and nine months after the operation: it was unusually free. For several months in the third year there was bleeding from the left nostril about every three weeks, but the patient informed her physician, Dr. D'Esterre, that she felt queer at monthly times though there was no show, and the epistaxis, although regular, was not synchronous with the molimen. This fact makes me distrustful about taking periodical bleedings beyond the area of the genital tract for "vicarious menstruation." I shall return to the subject when I relate the after-history of Case 82. In the fifth year this patient, Case 67, suffered from occasional but irregular attacks of pain in the left breast.

*Relation to cases in the old tables.*—In three cases (Cases 21, 49, and 53) both ovaries were saved and the catamenia remained regular more or less for over two years. In Cases 21 and 49 amputation was above the level of the os internum, in Case 53 there was some doubt about the level. In the two cases where there was no doubt about it the periods were still quite regular three years after the hysterectomy, whilst in the third, Case 53, the periods were regular at the end of the same space of time, but there had been amenorrhœa for three months in the second year after operation.[18] Thus in eight out of the 21 cases in this group, or over 38 per cent., making 8 per cent. in the whole series, both ovaries were saved and the periods continued for over two years after the operation.

*Analysis of the two cases where the catamenia were soon suppressed.*—Age: One between 40 and 45, Case 68; and one between 45 and 50, Case 91. Married or single: Both married. Hæmorrhages: Moderate in Case 91, and none in Case 68. Size of tumour: Large lobulated tumour, Case 91; 2 pound tumour, Case 68. Line of amputation: Above the os internum in both cases.

*Catamenia after operation.*—In Case 68 the periods continued regular for over a year and then ceased altogether; the patient, lean at the time of the operation, grew stout. There were no neuroses of any kind, and the patient's health was quite satisfactory four years after the operation. In Case 91 the patient was highly neurotic, and on that account I was anxious about preserving both ovaries and a piece of endometrium, and I was able to do so although one of the lobes burrowed into the right broad ligament. The patient, although 47 years old, had been perfectly regular until the operation, but from experience I find that a sudden artificial menopause induced near the climacteric may be as severe as when induced in a young subject. Her medical attendant, Dr. T. G. Styan of Ramsgate, carefully watched the case after operation. The phenomenon observed in Cases 51 and 53 in Group II. was present in this instance. Irregular show was observed at least three times, whilst fulness of the breasts, always associated with the periods before the removal of the uterus, occurred very regularly every month for a year and a half. Then they ceased and the patient suffered for a time from depression of spirits with irritability of temper; there were no flushings. The neurosis soon passed away, and the patient within three years after the operation felt free from all physical or mental discomfort. Had the operation been less conservative I suspect that the neuroses would have been more marked.

*Relation to cases in the old tables.*—As in the present tables, there were two cases in which the catamenia were soon suppressed. In Case 40 the period occurred three times after the operation and ceased abruptly, in Case 46 they continued for 18 months and also ceased abruptly, and as in Case 68 the sudden menopause was not associated with any neurosis. In Case 40 the line of amputation passed above the os internum, in Case 46 there was some uncertainty about the level of amputation. Thus, in 4 per cent. of the entire 100 cases, or over 19 per cent. in this group, both ovaries were saved and the catamenia were soon suppressed; neuroses were observed in only 1 out of the 4, and in that instance the patient was already neurotic.

*Analysis of the eight cases where the menopause was complete and immediate.*—Age: One between 35 and 40 (Case 65); two between 40 and 45 (Cases 70 and 94); three between 45 and 50 (Cases 82, 83, and 87); and two still menstruating, though aged, in one case 50 (Case 75) and in the other 52 (Case 92). Married or single: Four married (Cases 70, 75, 82, and 83) and four single (Cases 65, 87, 92, and 94). Hæmorrhages: Severe in Case 94; menorrhagia hardly severe in four cases (Cases 65, 82, 83, and 92) and none in three (Cases 70, 75, and 87). Size of tumour: 8 lb. 4 oz. in

[17] Cases 7, 8, 9, 11, 15, 18, 22, 32, 45, 48, 55, 56, and 59. In Case 11 flushings had been present before the operation.

[18] As in Case 20 in the "one ovary saved" series. In respect to these cases I noted in my first communication how they showed the importance of a fairly long after-history. At a year and a half both patients seemed to have reached the menopause. I have rejected several similar cases where the history could not be clearly traced for at least two years after operation.

*Subtotal Hysterectomy for Fibromyoma Uteri. Forty Additional Histories.*

| Case. | Date of operation. | Years of age, &c. | Character of fibroid. | Treatment of ovaries and line of amputation. | Date of last report. | Condition according to last report. |
|---|---|---|---|---|---|---|
| 61 | Feb. 19th, 1903. | 37, Md. | 11½ lb.; broad ligament opened up; hæmatoma of omentum, severe menorrhagia. | Both removed; above os internum. | May, 1909. | Strong and well, stouter; periods never seen since operation, flushings daily over face still. |
| 62 | March 3rd, 1903. | 49, Md.* | 2 lb. 6 oz., occupying whole posterior wall of uterus and cervix; metrorrhagia ten years; great anæmia. | One (left) saved; below os internum. | June, 1909. | Good health; show three or four times after operation; occasional flushings and vertigo still. |
| 63 | April 28th, 1903. | 43, S. | Bulky fibroid, extending above umbilicus and down into pelvis; menorrhagia. | One (right) saved; below os internum. | February, 1907. | Fair health, obesity; distinct show twice since operation; occasional flushings and vertigo still. |
| 64 | Oct. 15th, 1903. | 44, Md. | Fibroid, size of Tangerine orange, enucleated from anterior wall of supravaginal cervix; severe metrorrhagia, double aortic disease (see text). | Both removed; above os internum. | August, 1910. | Fair health, obesity; periods continued regular for two years; no flushings or other neuroses. |
| 65 | Nov. 12th, 1903. | 38, S. | 3 lb., hard, extending into pelvis; broad ligament invaded; menorrhagia, pressure symptoms. | Both saved; below os internum. | May, 1909. | Good health, gained flesh; no periods since operation, no flushings. |
| 66 | Dec. 12th, 1903. | 40, Md. | 15 lb., cystic perithelioma; rapid increase, tapped once; no menorrhagia. | One (left) saved; right ovary fibromatous; above os internum. | May, 1908. | Good health, obesity; no sign of recurrence, periods regular three years, no flushings (see author and Lockyer, "Two Cases of Uterine Fibroid showing Peritheliomatous Changes," *Journal of Obstetrics and Gynæcology of the British Empire*, xiv., 1908, p. 320). |
| 67 | Jan. 7th, 1904. | 27, S. | 2 lb. oval fibroid, pressing on bladder; no menorrhagia; temporary insanity after influenza four years before operation. | Both saved (see text); above os internum. | June, 1909. | Good health; periods regular for nearly two years, last period four and three-quarter years after operation; periodical epistaxis for about a year, when periods were disappearing; occasional pain, left breast. |
| 68 | Feb. 10th, 1904. | 41, Md. | 2 lb., bulky, rapid growth; no menorrhagia. | Both ovaries saved; above os internum. | March, 1908. | Good health, obesity; periods continued for over one year, no neuroses. |
| 69 | April 21st, 1904. | 48, Md. | 3½ lb. fibroid of cervix, portio vaginalis invaded; no menorrhagia; periods still regular. | Both ovaries removed (double hydrosalpinx); below os internum. | March, 1910. | Good health; one show shortly after convalescence, no flushings. |
| 70 | June 3rd, 1904. | 40, Md. | 8 lb. 4 oz., rapid growth; no menorrhagia. | Both ovaries saved; above os internum. | August, 1908. | Good health; no periods since operation, no flushings. |
| 71 | June 14th, 1904. | 34, Md. | Bulky fibroid in anterior wall, undergoing myxomatous degeneration; severe metrorrhagia; thickened endometrium removed by curette one month before operation. | Both ovaries saved; above os internum. | May, 1909. | Good health, obesity; periods still regular, coloured show four-weekly; occasional flushings third year. |
| 72 | June 21st, 1904. | 49, Md. | 1 lb. 9 oz. multiple interstitial myomata; menorrhagia one year. | One ovary saved; above os internum. | June, 1909. | Good health; periods regular for seven months after operation, then within six months irregular flushings and complete menopause. |
| 73 | Oct. 4th, 1904. | 43, Md. | 4 lb. hard fibroid, pressing on bladder; cervix and broad ligament involved. | Both ovaries removed; below os internum. | July, 1909. | Good health; no periods since operation, flushings once or twice weekly for a year and occasionally still; dyspeptic. |
| 74 | Nov. 3rd, 1904. | 41, S. | 6 lb.; large mass, extending into posterior wall of cervix; menorrhagia (exophthalmos, tachycardia). | One ovary saved; above os internum. | May, 1909. | Very good health; no periods since operation. |
| 75 | Jan. 24th, 1905. | 50, Md. | 2 lb. 12 oz. hour-glass fibroid, dragging on bladder; no menorrhagia. | Both ovaries saved; above os internum. | May, 1909. | Sickly; no periods since the operation; flushings, perspirations, and debility, continuing till date of last report. |
| 76 | Feb. 14th, 1905. | 38, S. | Large fibroid reaching above umbilicus, rapid growth; severe menorrhagia. | One ovary saved; above os internum. | May, 1909. | No periods since operation, no flushings; dyspepsia, occasional tympanitic distension of abdomen. |
| 77 | June 1st, 1905. | 42, S. | Fibroid in anterior wall of uterus, another in left broad ligament; severe pelvic pain; menorrhagia. | Both ovaries removed; above os internum. | September, 1910. | Slight show four times since operation; severe flushings and headaches for several months over three years after operation, then insanity, following mental shock and influenza. |
| 78 | June 17th, 1905. | 36, Md. | 2¼ lb. "cystic perithelioma," rapid growth; emaciation, menorrhagia. | Both ovaries removed; above os internum. | February, 1908. | Good health, no sign of recurrence; no periods since operation, flushings one year (see author and Lockyer, loc. cit., No. 66). |
| 79 | July 6th, 1905. | 43, S.† | 8 lb. 2 oz., rapid growth, no menorrhagia. | One ovary saved; above os internum. | July, 1909. | Good health; periods regularly for one year after operation, last show about six months before date of last report. |
| 80 | Oct. 24th, 1905. | 35, S. | 2¾ lb.; menorrhagia (adenomatous polypus discovered in uterine cavity). | One (left) ovary saved; above os internum. | November, 1910. | Good health; periods regular but very scanty, no flushings. |
| 81 | Dec. 12th, 1905. | 44, S. | 7 lb. 2 oz. invading broad ligament; painful pressure symptoms; slight menorrhagia. | Both removed (corpus luteum hæmatoma in left); above os internum. | May, 1909. | Good health: no periods since operation, occasional flushings. |
| 82 | Jan. 23rd 1906. | 47, Md. | 7½ lb.; very firm pressure symptoms, menorrhagia (see text). | Both saved; above os internum. | July, 1908. | Fair health, plethoric (see text); parametritic abscess and sinus, no show of blood from vagina after operation; blood escaped from sinus (see text) regularly for three months, then irregularly with flushings; last show two years and four months after operation, then flushings ceased. |

* Still menstruating. † Sister to Nos. 6 and 12.

*Subtotal Hysterectomy for Fibromyoma Uteri. Forty Additional Histories (Continued).*

| Case. | Date of operation. | Years of age, &c. | Character of fibroid. | Treatment of ovaries and line of amputation. | Date of last report. | Condition according to last report. |
|---|---|---|---|---|---|---|
| 83 | Feb. 1st, 1906. | 46, Md. | 2½ lb., three lobes, one submucous; menorrhagia. | Both ovaries saved; below os internum. | October, 1908. | Fair health; no periods since operation, no flushings. |
| 84 | March 21st, 1906. | 38, Md. | Small three-lobed tumour; broad ligament opened up; pressure symptoms, no menorrhagia. | Both ovaries removed; below os internum. | June, 1909. | Good health; no period since operation, severe flushings and perspirations for a few months after operation. |
| 85 | May 15th, 1906. | 40, S. | 1 lb. 1 oz., multiple fibroids, some submucous; severe menorrhagia. | Both ovaries saved; above os internum. | May, 1909. | Good health; periods still present though scanty; flushings and faintness after each period till two years and five months after operation; obesity. |
| 86 | May 17th, 1906. | 38, Md. | 1 lb. 2 oz., spherical fibroid; menorrhagia. | Both ovaries saved; above os internum. | June, 1909. | Good health; periods still present and regular, occasional pains at periods, no flushings. |
| 87 | June 26th, 1906. | 45, S. | 2 lb. 1 oz.; increasing quickly; abdominal pains; no menorrhagia. | Both ovaries saved; above os internum. | May, 1909. | Good health, except dyspeptic pains; no periods since operation, no flushings. |
| 88 | June 28th, 1906. | 46, S. | 2 lb. 5 oz., pedunculated myoma and small interstitial myoma in anterior wall; cyst left mesometrium below ovary, dysuria, no menorrhagia; hæmoptysis at 31. | Right ovary saved; above os internum. | May, 1909. | Good health, gained weight; no advance of pulmonary symptoms; no periods since operation; recently occasional flushings and perspirations. |
| 89 | July 10th, 1906. | 41, S. | 1¼ lb., multilobular; left broad ligament opened up; pressure symptoms; menorrhagia. | One ovary saved, the other was cystic and contained large hæmatoma; above os internum. | June, 1909. | Quite well; periods regular, though scanty, no flushings. |
| 90 | July 17th, 1906. | 41, Md. | 3¼ lb., cervix involved, rapid growth; abdominal pains, dysmenorrhœa, no menorrhagia. | Both removed (cystic); below os internum. | June, 1909. | Good health, obesity; no periods since operation. |
| 91 | Oct. 29th, 1906. | 47, Md. | Large multilobular fibroid; no menorrhagia. | Both ovaries saved: above os internum. | June, 1909. | Good health; periodical molimen (see text) for a year and a halt, with show on three occasions; then "depressed spirits" for a month or two, no flushings. |
| 92 | Nov. 20th, 1906. | 52, S. | Mass of interstitial fibroids; pressure symptoms and menorrhagia. | Both ovaries saved; above os internum. | March, 1910. | Good health; no periods after operation; no neuroses. |
| 93 | July 16th, 1907. | 50, Md. | Highly-lobulated fibroid, left mesosalpinx opened up; adhesions to mesentery, chronic obstruction; periods still present, becoming irregular. | Both ovaries removed; above os internum. | January, 1910. | No periods since operation; no menopause symptoms (see author, "Chronic Intestinal Obstruction due to Adhesions of a Uterine Fibroid to the Mesentery," THE LANCET, Nov. 9th, 1907, p. 1309). |
| 94 | July 23rd, 1907. | 42, S. | 2 lb. 6 oz., uterus infested with small fibroids; menorrhagia, recently amenorrhœa; great anæmia. | Both ovaries saved; above os internum. | August, 1909. | Good health, gained colour and flesh; no periods since operation; moderate flushings three to five months after operation; occasional tenderness in region of right ovary. |
| 95 | July 28th, 1907. | 41, Md. | 3 lb. 2 oz., rapid growth; menorrhagia. | One ovary saved; above os internum. | July, 1909. | Good health; no periods since operation, no flushings. |
| 96 | Sept. 22nd, 1907. | 38, Md. | Polypus (adenoma) removed January, 1906; hæmorrhages, August, 1906, till operation; interstitial growth as big as a walnut, also a submucous adenoma. | Both ovaries removed; a little below os internum. | September, 1910. | Good health, obesity; no periods since operation; no menopause symptoms. |
| 97 | Nov. 5th, 1907. | 38, S. | Large sessile subserous tumour, 4 in. diameter, and smaller but similar tumour, both on posterior aspect of uterus; pressure symptoms, no menorrhagia. | Both ovaries saved; 1 in. above os internum. | December, 1909. | Good health; periods still regular, four-weekly, except on two recent occasions, when interval was only two weeks. |
| 98 | Jan. 21st, 1908. | 35, Md. | 4¾ lb., deeply lobulated, one lobe blocking Douglas's pouch; no menorrhagia. | Right ovary saved; above os internum. | January, 1910. | Good health; slight, regular periods for a few months after the operation; flushings and headache. |
| 99 | Jan. 28th, 1908. | 38, Md. | Fibroid size of turkey's egg on fundus, retroversion; right hæmatosalpinx, many adhesions; no menorrhagia; see "Hæmatosalpinx with Acute Symptoms following Retroversion of Fibroid Uterus," Proceedings of the Royal Society of Medicine (Obstetrical Section), i., p. 174. | Both ovaries removed; above os internum. | January, 1910. | Good health, gained flesh; no periods since operation, but severe hot flushes regularly for a few months, now about every two months and less severe. |
| 100 | Feb. 6th, 1908. | 28, S. | 1 lb. 8 oz. firm fibroid posterior wall, growth rapid; menorrhagia. | Left ovary saved; ½ in. above os internum. | February, 1910. | No periods after operation; no unpleasant symptoms. |

Case 70; 7½ lb. in Case 82; 3 lb., opening up broad ligaments, in Case 65; 2 lb. 12 oz., dragging on bladder, in Case 75; 2 lb. 10 oz. in Case 87; 2½ lb. in Case 83; 2 lb. 6 oz. in Case 94; and small in Case 92. Line of amputation: Above the os internum in five (Cases 70, 82, 87, 92, and 94) and below in three (Cases 65, 75, and 83).

*History after operation.*—In five cases (Cases 65, 70, 83, 87, and 92) there was no show of any kind, and none of the patients suffered from flushings or other neuroses. Cases 75, 82, and 94 deserve some consideration. Case 75, age 50, married 29 years; first husband lived 20 years; patient remarried shortly after his death; second husband still living. Never pregnant. Hæmorrhages: No metrorrhagia. Notwithstanding the patient's age, the periods were absolutely regular, there was free show for about three days associated not with pain, but with a feeling of languor. Size of tumour: A large lobular mass weighing, with uterus, 2 lb. 12 oz.; the anterior lobe sprang from the anterior wall, the posterior from the posterior wall of the uterus. The posterior lobe had fallen back into Douglas's pouch which it filled, the cervix was raised high up behind the pubes, and the anterior lobe tipped upwards so as to drag on the bladder. Its upper limits lay within three inches of the umbilicus. Line of amputation: Below the os internum.

*Catamenial history after operation.*—In May, 1909, the patient, in reply to my inquiries, wrote: "I have not seen any monthly period since my operation. I suffer very much with flushings and perspirations of the face and lower parts, at times." She also had bleeding hæmorrhoids and neglected pyorrhœa alveolaris. Before the operation this

patient was a stout woman, with suborbital pigmentation and marked pyorrhœa, which, as above stated, she neglected after convalescence. She had never suffered from any serious illness. The pulse and temperature were normal. She had been under Mr. A. C. Butler-Smythe's observation for a few weeks owing to extreme dysuria caused by the falling back of the tumour, as above mentioned. The operation was not very easy owing to the shape of the mass; there was a heavy drag on the broad ligaments which were clamped and divided, then the tumour was drawn out of the wound, but I was obliged to amputate low down, below the os internum. The after-history is mainly of interest in respect to the conditions noted above as reported before the operation. The patient's menopause was belated; perfectly regular up to the date of operation, it never reappeared afterwards. The pyorrhœa could not fail to have a bad influence on the patient's health, but one fact remains—namely, the appearance of characteristic flushings such as are observed both in healthy and in sickly women in the natural, and also in an artificial, menopause. In my reference to Kelly and Cullen's opinion on the question under consideration, I explained how I thought it advisable to record instances of late artificial menopauses of which Case 75 was an eminent and instructive example. Many natural menopauses in healthy women are more severe, and a subject with pyorrhœa cannot be called healthy. Would the flushings have been milder or absent altogether had the amputation been made above the os internum? Would they have been more severe had the ovaries been removed? I feel fairly sure that a positive reply may be given to the latter question. The former, however, cannot be solved; we cannot calculate how far age and the disease existent at the time would prove disturbing factors, however beneficial the saving of the endometrium might be. Kelly, as I have explained, has recently introduced a method of operation designed to preserve endometrium. I hold it very important that late artificial menopauses, as well as earlier ones, should be carefully reported if we desire a thorough knowledge of the value of this conservative step, one of the main questions to which I have turned attention in this communication, and on that account I have dwelt on Case 75 at some length.

In Case 82 a troublesome complication occurred which raises once more the question of vicarious menstruation. Age 47, married 30 years, two children and one abortion; the second child was 27 years old; the abortion occurred a year earlier. The patient was robust, plethoric, and subject during recent years to attacks of vomiting. The urine occasionally contained a trace of albumin. Catamenia occurred every three weeks, lasting for nine days; the show was very free and clots were expelled after attacks of pain compared by the patient to those of parturition. Size of tumour: It was multilobular; one lobe reached to the left hypochondrium. I operated in January, 1906. When the big lobulated mass was drawn out of the abdominal wound I met with some difficulty in reaching the front of the cervix owing to the presence of two subserous fibroids projecting from the lower segment of the uterus. I made a serous flap by dividing the peritoneum over the fibroids horizontally and turning it down. The uterine arteries were then secured, but in reaching the right artery and vein, the parametric connective tissue, hyperplastic and hyperæmic, was unavoidably subjected to much handling. I amputated the uterus a little *above* the cervix. The stump, which was not very fleshy, was covered over with the serous flap, No. 3 Van Horn catgut being employed. The right parametrium suppurated and the abscess was opened by an incision in the right groin on March 9th.

*History after operation.*—No show of blood passing from the vagina was ever observed after the operation. The sinus gave great trouble, and in the last weeks of July, August, and September, 1906, about the time that the period was due, the patient noticed that blood issued freely for several days from its orifice. Flushings with sensations of fulness in the head came on. On March 18th and April 17th, 1908, blood began to escape from the sinus and to discharge steadily for three days, ceasing abruptly at the end of that space of time. In the week ending May 23rd, 1908, the same phenomenon occurred when the patient was under my observation. The flushings then ceased, and I understand that the periodical discharge of blood has not recurred. The patient's general health remained good, although there was some œdema of the right leg, but the plethora and stoutness were more marked than before the operation, when I last saw her in the summer of 1908.

I think it right to record this case where the after-history was somewhat unsatisfactory. I do not think that the infection must have certainly been derived from the piece of endometrium left in the stump. The tissues in the right parametrium were opened up and the catgut used for the flap probably carried infection into the parametric tissue. I had some trouble with catgut in other cases at the same time, and complications ceased when I discarded that which I had in store and made use of the same material from another stock. The more we learn through experience how to ward off infection the fewer will such cases become even when we spare some endometrium. Not many years ago the tolerably regular hæmorrhages from the sinus would have been reckoned by most gynæcologists as "vicarious menstruation." But in relating Case 67 I noted how Dr. D'Esterre reported that the molimen was regular for some time without show, whilst there were regular attacks of epistaxis, but the molimen and the epistaxis were not synchronous. In Case 82 there was no regular molimen, but the hæmorrhages recurred monthly for three months in the first and in the third year, being associated on the latter occasion with flushings. It is much more likely that the hæmorrhages in Case 82 were directly related to the catamenial function, but I am sure that no physiologist would feel certain about their precise signification.

Case 94: The patient was a single woman, aged 42 years. Hæmorrhages: Chronic menorrhagia, causing great anæmia; more recently no regular period, but irregular passage of clots. Size of tumour: A bilobed, hard mass occupying the right iliac fossa; the outer was a subserous spherical fibroid about 2 inches in long diameter, the inner being the body of the uterus infested with small interstitial fibroids; there were also three small growths of the submucous type all fibromyomatous. No adenomatous polypus existed. The whole weighed 2 lb. 6 oz. Line of amputation: Above the os internum.

*Catamenial history after operation.*—I examined the patient two years and one month after the removal of the tumour. There had been no period since the operation. In the course of the first year she had lumbar pains like the molimen which occurred at the beginning of the normal periods before her illness, but this molimen was never regular for several months as in Case 91. At the same time there were occasional flushings. Whilst these phenomena were present the anæmia caused by the hæmorrhages from the fibroid steadily disappeared, the patient's complexion became rosy, and she gained flesh without growing corpulent. The right ovary was slightly enlarged and tender to the touch. The flushings were probably associated with the changes in the circulation due to the removal of the sole cause of anæmia. The same symptom, but far more severe, was present for a time after operation on one of the worst cases of bleeding fibroid I have ever had under my charge, but as it must be numbered 102 in my series of hysterectomies for fibroid with authenticated after-histories, it could not be included in these tables. The patient was greatly reduced by periodical bleedings which had gone on for nine years. Both ovaries were removed, being diseased; the uterus was amputated above the level of the os internum. For a few months flushings with "attacks of a very cold sensation" gave trouble but completely disappeared, and the patient, 44 years of age, was in good health two years after the operation. This case is not under the same group as Case 94, but in both the sudden stoppage of prolonged hæmorrhages have to be taken into account.

*Relation to cases in the old tables.*—Only one case (Case 50) came under the present group. There was a little show of blood for five weeks about 14 months after the operation, but this show could hardly be reckoned as catamenial. Nearly one year later it had not recurred. The patient was then under the impression that she occasionally felt a slight molimen. She was only 30 years of age when the uterus was removed. This case is really akin to Cases 65, 70, 83, 87, and 92; the molimen, however, should, I suspect, be better ranked as a neurosis. Thus in 9 per cent. of the 100 cases, or in over 42 per cent. of this group, both ovaries were saved and the menopause was complete and immediate. Altogether the results were favourable, though in three (Cases 75, 82, and 94) troublesome symptoms

developed, but certain complications had to be taken into account.

*Summary of the Complete Series of 100 Cases.*

In 40 cases, or 40 per cent., *both* ovaries were *removed*, and the menopause was neither immediate nor complete in 4; in 3 out of the 4 the amputation was above the os internum. In 39 cases, or 39 per cent., *one* ovary was *saved*, and the menopause was neither immediate nor complete in 21; in 18 out of the 21 the amputation was above the os internum. In 21 cases, or 21 per cent., *both* ovaries were *saved*. The menopause was neither immediate nor complete in 8; in 7, possibly all, of the 8 the amputation was above the os internum.

Granville-place, W.

## GANGRENE OF LIMB DURING CONVALESCENCE FROM DIPHTHERIA.

BY A. S. RANSOME, M.A., M.B., B.C. CANTAB., D.P.H.,
PHYSICIAN TO THE ISOLATION HOSPITAL, SOUTHGATE; SURGEON TO THE HOSPITAL, BOWES PARK;
AND
EDRED M. CORNER, M.C. CANTAB., F.R.C.S. ENG.,
SURGEON TO THE CHILDREN'S HOSPITAL, GREAT ORMOND-STREET, AND TO ST. THOMAS'S HOSPITAL IN CHARGE OF OUT-PATIENTS; CONSULTING SURGEON TO THE HOSPITAL, BOWES PARK, ETC.

BY diligent search in the libraries of the Royal Society of Medicine and of the Royal College of Surgeons of England it has been possible to find records of nine cases of gangrene following diphtheria. We do not mean gangrene of the parts near the situation of the disease, such as sloughing of throat or tonsils; we refer to gangrene of parts distant to the disease, such as of a limb. That such occurrence is very rare is proved by the fact that Dr. F. F. Caiger of the South-Western Fever Hospital in 17 years' work had never heard of a case, as well as by the paucity of records in the literature. In consequence it struck us that it would be a useful work to collect, together with our case, the various items of knowledge of this rare event, so widely scattered through the literature, making nine cases in all. In connexion with this we acknowledge our thanks to Dr. J. D. Rolleston of the Grove Hospital, Tooting, for the details in his letter to Dr. Caiger.

The gangrene in the cases mentioned above was connected with a definite vascular lesion. In seven cases the lesion was a definite embolism; in one it is termed Raynaud's disease, and in two the origin is as obscure as the papers published in Madrid and Venice about 24–34 years ago, and now unobtainable. In no less than 6 out of the 9 cases the leg was affected; in one there were widespread gangrenous lesions in addition. In two other cases there was a widespread necrotic affection. Thus it would appear that in 6 out of the 9 cases the gangrene was due to a vascular lesion, and that in 2 it was due to a vascular lesion with the addition of an infective or septic character in the embolus. In only one case, that which we now record, was the diphtheria treated with antitoxin. The majority of the patients naturally were children.

The origin of these emboli seems to be in the auricles, particularly the left auricle, because in only one case was there also a pulmonary embolism. The embolus occurs during convalescence, at the time of reaction from the illness; in our case on the seventeenth day of the illness. It seems to occur only after a severe diphtheritic attack. Subsequently to the embolism the temperature rose to 99·8°F. from subnormal, to which level it subsided, rising again in a few days' time from septic absorption from the gangrenous part.

It is a curious fact that surgically the femoral or popliteal artery can be ligatured in young subjects without causing gangrene. And yet a post-diphtheritic embolus should cause gangrene. The difference must be due to a thrombus extending from the embolus; and in diphtheria, we would suggest, a arteritis, having arisen from endarteritis, preventing the dilatation of the branches to form an anastomotic circulation and aiding the extension of the thrombus; in addition there is the dystrophy of the diphtheritic paralysis and the possibly infective condition of the embolus.

We will give a full account of our case first and then reproduce briefly those obtainable from the literature.

*Diphtheria; threatened cardiac failure; albuminuria; paralysis; gangrene of foot; amputation of leg; recovery.*—The patient was a boy, aged 6 years. The illness began on Nov. 28th, 1908, with shivering and vomiting. On the 29th the throat was sore but no membrane was visible. On the 30th there was a thick membrane on the throat. 4000 units of antitoxin were injected and the patient was removed to Southgate Isolation Hospital. Dec. 1st: Antitoxin, 4000 units injected. 4th: A piece of tough blood-stained membrane, 2 inches by 1 inch, was syringed from the throat. 5th: Vomiting and pains in the stomach. 12th: The patient vomited for four hours and was threatened with collapse and cardiac failure. The pulse could not be felt and the extremities were cold and the condition remained much the same for three hours. There was gradual improvement during the night, but no nourishment could be retained. 13th: The vomiting still persisted. All nourishment by mouth was stopped except water given in a spoon occasionally. 14th: Nutrient enema of eggs, milk, and brandy given every four hours. 15th (seventeenth day): Very acute sudden cramp in the right leg, the patient screaming with agony. Hot flannels and bathing in hot mustard-water gave temporary relief. 16th: Cramp at frequent intervals, relieved by laudanum fomentations. 17th: The right foot and leg were slightly discoloured in patches, giving the appearance of bruises. 18th: The patches of discolouration over the right foot and leg up to the knee were more marked and were purple in colour, the patches over the foot and lower part of the leg being larger and darker than those higher up. The urine was very scanty; albumin ½. Taking milk from spoon. 19th: Nutrient enemata discontinued. Albumin ¾; no vomiting. 22nd: Albumin down to ½ again. The patches of discolouration at the upper part of the leg were beginning to fade and subside, while those over the foot and lower part of the leg were larger and deeper in colour. The leg was tender. 24th: No albumin. The leg was kept wrapped up in wool. 25th: A little chicken and vegetable given. 28th: The patient was feeding well, taking three eggs daily. The discolouration of the leg had practically subsided down to below the juncture of the middle and lower third of the leg and foot. The patches over the foot and the lower part of the leg had coalesced so that the foot was one even purple colour. Jan. 1st, 1909: The patient complained of pain in the foot and leg; he kept the leg flexed and lying on its outer side, and resented its being touched. 3rd: A blister appeared on the ankle, and the toes were black, dry, and shrivelled. 4th: Fluid nourishment produced coughing. The voice was very nasal, and the general condition very paralytic. 5th: The patient was very weak and he seemed to be sinking. He had great difficulty in swallowing, especially solid food. 7th: The patient was gradually improving, but the pulse, which had been very rapid all along, was still so—130 to 160. He slept well. 15th: Improvement maintained; well-marked line of demarcation at the junction of the lower and middle third of the leg, and sloughing rapidly immediately below the line of demarcation. 30th: The leg was amputated just below the knee. On Feb. 12th the stump had quite healed and the pulse was normal. The patient was in excellent health and was putting on flesh. On March 15th he was discharged.

During the operation, on the forty-sixth day after the embolism and the sixty-first of the illness, the popliteal artery was divided just above its bifurcation. Its lumen was free from clot; it was markedly small and the walls were thin. Hence the embolus was above the bifurcation of the popliteal artery, possibly in the femoral artery at the bifurcation of the superficial femoral. This is supported by the clinical observation that on the third day after the embolism (Nov. 18th) the discolouration reached the level of the knee. The discolouration receded from the knee as the anastomotic circulation improved, and finally established a line of demarcation three inches above the ankle. After the amputation the arteries in the stump were followed until they deliquesced. Their lumina were small but free from clot.

*Brief Details of Cases taken from the Literature of the Subject.*

POUPON. *Embolie de l'artère fémorale dans la convalescence de la diphthérie* (*Le Progrès Médical, 1883, p. 10*).—Patient, aged 7½ months, admitted on Feb. 17th, under the care of Dr. Bouchut for "croup." Tracheotomy on the same day by M. Launois. She was discharged March 2nd, with the wound completely closed, and in very satisfactory health. During her first stay in hospital the urine showed some

albumin, but there was none subsequently. Readmitted on March 13th with intense dyspnœa, fever, and facial pallor. She was said to have discharged some false membrane in the interval, but expectoration of masses of mucus are often mistaken for such by parents. There was no diphtheritic paralysis. Temperature 102° F.; respirations 40 per minute. Dulness at base of right lung. At this level there was a slight expiratory murmur with pleuritic rub. Dr. Bouchut diagnosed pulmonary embolism. Auscultation of the heart was not performed thoroughly on account of the respiration causing a considerable murmur over the tracheal wound which had reopened. Pulse 80. March 14th: Patient complained of pain over the right popliteal space. In the evening there were violet-coloured patches over the whole foot; they were of the size of a franc-piece and the violet hue was that of gangrene. The leg was cold and the pulsations in the popliteal, and even in the femoral artery were imperceptible. The temperature was 31° C. in the right leg and 37° C. in the left. Sensation was absolutely abolished at the level of the patches of gangrene. Next morning (March 15th) Dr. Bouchut diagnosed embolism of the popliteal artery. The child died an hour after his visit.

Necropsy permitted on leg only. In the crural artery, starting from the ring of the great adductor, and proceeding to the centre of the popliteal, a clot three centimetres long was found looking like a pencil. The clot was brownish-grey in colour and was not adherent to the wall. Here and there it showed clearer striæ. It occupied the whole lumen of the artery.

It seems clear that the clot in the femoral artery was due to an embolus around which the thrombus had formed, composing, as in all cases of this nature, almost the whole of the clot.

HYDE AND POWELL. *Case of Raynaud's disease following diphtheria (Brit. Med. Jour., 1886, vol. i., p. 203).*—Patient, aged 48 years, was admitted to Worcester General Infirmary on July 14th, 1884. He had been in the Royal Horse Artillery for 22 years, and was drill instructor to the police for six years. No illness except one or two "colds" from wet feet when on night duty. No syphilis, gout, or rheumatism. Family history good. On May 12th he reported himself ill with sore-throat. A week later he had sudden loss of voice, for which he was treated by a practitioner who said that he had diphtheria. During convalescence his nose became blue and swollen in one night, resembling "an overgrown mulberry." This was followed in a day or two by similar appearances in pulps of finger of the right hand and in the ears. In the following week the ring and little finger of the left hand were similarly attacked, causing pain. In three weeks the fingers were black along their entire length. The blackness then receded to the middle joints, where blebs formed between the sound flesh and mortified parts. Subsequently black patches formed on the second and third toes of the right foot and along its outer margin. His mouth and tongue became swollen and painful, the latter being livid and an ulcer forming near the lip. His nose was obstructed but was cleared by his sneezing out some tough brown matter.

Examination day after admission: Well built, fairly healthy looking; had lost some flesh and become weaker from illness. Hair grey; no arcus senilis, nor signs of general anæmia. Nose cold and livid. Edges of helices of both ears dark blue. Ungual, and part of middle phalanges of ring and little fingers of right hand were black, dried up, and completely mummified. The fingers of the left hand and both thumbs were cold, glossy, devoid of hairs, and of dusky red colour at the tips. Ungual phalanges of second and third toes of the right foot were also sphacelated. Sphacelated portions of fingers were separated from sound flesh by bullæ containing turbid serum. Physical examination showed chest normal. Radial, ulnar, and posterior tibial arteries normal. No paralysis, sensory or motor. Voice regained. Temperature normal. Urine contained little albumin, no casts or sugar. Blood showed increase of white corpuscles. Digestive functions good. Slight pain and tingling in fingers occasionally.

Improved rapidly under dietetic and tonic treatment. Went for change of air on Sept. 3rd. The gangrenous fingers were amputated on his return. Sloughs separated from ears on his return. Sloughs separated from ears and toes without interference, leaving granulating surfaces beneath which healed rapidly. Stumps of gangrenous fingers slow in healing; thumbs and ears still cold and discoloured, but he was well enough to resume work.

BRETON (M.). *Paralysie Méta-diphtérique. (La Médecine Moderne, Paris, 1902, Vol. XIII., p. 216. Société de Pédiatrie-Séance de 17 Juin, 1902.)*—M. Breton has had under his observation a little girl, aged 3 years, suffering from hemiplegia due to multiple embolism, the sequela of diphtheria. The child suddenly manifested paralysis of the right side, and at the same time livid patches, followed by gangrene, appeared on the left leg. The hemiplegia persisted for eight months, although the child had the power of walking—dragging the leg along. There had been present in this case without doubt endocarditis, cardiac thrombosis, and multiple embolisms.

VEDDER (JOHN). *Gangrene of the leg caused by embolism following diphtheria. (Transactions of Medical Society, State of New York, 1879, p. 259.)*—A boy, aged 8 years, whose health had been generally good. First visited on Dec. 21st, 1877. Diphtheria, severe attack, but prognosis favourable. Throat and nares covered with thick membranous deposit; profuse discharge from nose; breath offensive; slight constitutional disturbance; fever moderate. Was visited every day up to the 29th. A sister was taken ill with the disease meanwhile. Continued to visit her after convalescence was established in the boy. On the 31st there was nothing unusual in the boy's condition; convalescence progressing well. In the afternoon of the same day he complained of numbness and pain in the right leg from the knee downwards; pain mostly in the knee, and below that there was sensation of numbness. Leg cold and of waxy appearance. Knee only painful, and upon slightest motion. Pain could not be produced in the leg either by pinching or pricking with needle. Leg dead from knee downwards; it was white and cold. On the next day the leg was of light mahogany colour, which gradually grew darker till it was nearly black. The bottom of the foot became quite dark, dry, hard, and shrivelled up in a few days. Pulse slow and weak at right wrist; normal at left. Respiration good. Mind clear. Jan. 5th or 6th: Arm on right side paralysed. Jan. 6th and 7th: Slight paralysis of tongue and loss of speech. The boy died on Jan. 11th at 2 A.M. He was conscious during the whole illness till a few hours before death. Two days before he had complained of pain in the left leg when it was moved. The patient was of excitable temperament. No necropsy.

# IMPORTANCE OF REMOVING THE UTERUS IN CERTAIN DISEASED CONDITIONS OF THE ADNEXA.[1]

BY J. M. MUNRO KERR, M.D. GLASG.,
GYNÆCOLOGICAL SURGEON, WESTERN INFIRMARY, GLASGOW; OBSTETRIC SURGEON, GLASGOW MATERNITY HOSPITAL.

ALL gynæcologists of experience, and especially those of obstetric experience, appreciate fully the necessity of conservative surgery in dealing with diseases of the uterus and adnexa. For example, we perform myomectomy rather than hysterectomy, resection of the ovary and tube rather than removal of these organs in women who have not passed the reproductive age; and all of us, I feel sure, can give examples of pregnancies occurring and continuing to term after such operations. Only the other day a medical man informed me that a patient, upon whom I had operated two and a half years ago and where I was only able to save one tube and a small portion of the ovary, had given birth recently to a full-time healthy child.

Appreciating so fully the importance of conservative treatment of the organs we have to deal with, I think we occasionally fall into the mistake of not being radical enough in our operative procedures in those cases of extreme disease where it is obvious that nothing can be done by conservative measures. We are especially inclined, I think, to leave the uterus behind in certain ovarian and grave tubal conditions when we would obtain much better results, both immediate and remote, if we removed the uterus along with the diseased adnexa.

As far as one can judge at present, and the recent researches of Carmichael contributed to this society go to support this, the uterus is merely a bag for retaining the impregnated ovum. It contributes no internal secretion.

I now wish to direct attention to two diseases of the adnexa in which I believe it to be of the very greatest importance that the uterus should be removed along with the appendages. The two diseases I wish to refer to are malignant disease of the ovary and pronounced pyosalpinx.

### *Malignant Disease of the Ovary.*

The frequency of malignant disease in ovarian tumours is variously stated, but it would appear to be found in about 15–20 per cent. of all cases operated upon. In my own experience it has not been quite so high as this.

Within the last year or two it has become my custom in all doubtful malignant tumours, and in all double ovarian tumours, to remove the entire uterus along with these growths. My reasons for adopting this radical treatment are twofold. First of all the experience of other operators that more satisfactory results are obtained with such procedure, but particularly my own personal experience in a few cases, which I shall now very briefly refer to.

Two and a half years ago a patient with an ovarian tumour was sent to me and I opened the abdomen and removed the growth, and the pathologist reported it was a sarcoma. About a year later I had to remove the uterus for malignant disease; at the time of the first operation the uterus and other ovary appeared perfectly normal.

Another case was one in which I saw a patient who

[1] A paper read at a meeting of the Edinburgh Obstetrical Society.

had been operated upon for ovariotomy and who presented features of malignant disease of the uterus and surrounding parts nine months later; at the time of the first operation the surgeon had not deemed the condition malignant.

Twice I have seen a co-existing adeno-carcinoma of the uterus and carcinoma of the ovary. I show you here the coloured drawing of the second case, and you will observe at a glance that I could easily have removed the malignant growth of the one ovary and left behind the other healthy ovary with the uterus apparently healthy. Such a proceeding in this case would have been most unfortunate, for the malignant growth in the uterus would probably have been allowed to continue for some time before a second operation was thought of.

The real practical difficulty is in deciding in many cases when the growth of the ovary is malignant.

About six weeks ago I operated upon a lady for an ovarian tumour. It was connected with the left ovary and was burrowing down into the cellular tissue about the rectum; the other ovary was also diseased, and so I removed both ovaries and the entire uterus. I hardly thought the ovarian growth was malignant, but I had the specimen very carefully examined. I was greatly surprised to get the report from Dr. J. H. Teacher that a small portion of the growth showed evidence of early malignancy.

It is my practice now to remove both ovaries and the uterus in all growths that look malignant or suspiciously malignant, and to remove the entire uterus and ovaries in all bilateral ovarian growths where the ovaries are hopelessly destroyed.

*Pyosalpinx.*

The other condition to which I wish specially to refer is pyosalpinx. The cases of this group, however, which I intend dealing with are only those cases of extreme salpingitis. I will not refer at all to the milder cases of salpingo-ovaritis, in which portions of the ovaries and tubes can often be conserved, and where the operation is of no great difficulty.

In common with most gynæcological surgeons, it used to be my custom to remove the pus-tubes and leave the uterus behind. In many cases I found it extremely difficult to remove the tubes, and I very frequently ruptured them during the operation. My results were moderately satisfactory, for I had a mortality of about 10 per cent. What disappointed me, however, was that in not a few cases the patients continued to have a certain degree of abdominal uneasiness, and in one or two cases so great was this that I was compelled later to remove the uterus. It was chiefly for this reason that I abandoned this method of dealing with the condition.

During the last two and a half years I have in all cases removed the uterus along with the distended tubes. My results from such a procedure have been infinitely more satisfactory than formerly. Neither in my private nor in my hospital cases have I had a single death, and that in spite of the fact that I have had to repair tears in the bowel more than once, and on three occasions have been compelled to resect large portions of the gut. In carrying out the operation I have only twice ruptured the sac. I am quite prepared to admit that rupturing a pyosalpinx during operation is frequently attended with no ill-effects, for in so many cases the pus is sterile and the individual has become immune to the particular organisms present; still, in a few cases pus tubes contain most virulent organisms and these in a very active state. More particularly is this seen in cases where the salpingitis has followed a comparatively recent parturition.

About a year ago I removed with extreme difficulty the uterus and pus tubes in a case of pyosalpinx, which resulted from an infection after an abortion. The patient was lying in my ward in the Maternity Hospital for several weeks. Occasionally she was a little better and the febrile disturbances subsided, but for the greater part of the time she had a temperature of 100° to 101° F., running up sometimes to 102° and 103°. I removed these tubes and uterus without spilling any pus, and I was well pleased that I had succeeded in doing so, for the pus gave a mixed culture of streptococcus and bacillus coli.

In connexion with the spilling of pus, although it is very generally not of very serious moment as regards causing a general peritonitis, it is very apt to lead to the infection of the fresh abdominal wound, and we all know how important it is that the abdominal wound should heal without the slightest suppuration.

In dealing with pyosalpinx my practice is as follows. I make an extensive longitudinal incision; in such cases it is a great mistake to have one's incision too small. I then carefully pack off the intestines as far as I can with rolls of sterilised gauze. I then surround the wound completely with gauze and place a Doyen's retractor at the lower part and self-retaining lateral retractors at the upper part. My whole field of operation then and the abdominal wound are completely protected with gauze. I then carefully examine the condition of the uterus and tubes, and the relationship of the intestinal adhesions to these parts. Having done so, I seize the uterus with a volsellum forceps, so as to steady that organ. I next make up my mind which tube can be most easily dealt with, for in most of the cases I have found it best to go down the easy side and cut across the cervix, and approach the larger pus sac from below. In a few cases I have found it possible to separate each side and clamp off the broad ligament and remove the uterus, just as one does in an ordinary hysterectomy for fibroids, but that has been the exception. I have only twice bisected the uterus, and I am always loth to do this, because it also is infected. Where there are extensive adhesions—and in almost all my cases these have been present—I sponge off the intestine with gauze. Usually the intestines come off easily from the posterior wall of the uterus, but very frequently, indeed, the tubes are extremely intimately blended with the bowel.

The separation of the bowel from the pyosalpinx is often a matter of great difficulty. As I have already indicated, however, one side is usually easy of approach. Once or twice I have pushed down the bladder and cut across the cervix before attempting to separate the tubes. By that means, and by dividing the upper margin of the broad ligament, one is able to approach the sac from all sides, and that is a great advantage. It is very comparable to the homely operation of separating a postage stamp from an envelope without tearing the stamp. One can often do this if one can get round the edges of the stamp, while if one attacks it from below or above it tears across.

In dealing with pyosalpinx in this manner great care must be taken, after dividing the cervix and working up from below, that the ureter is not injured. I have once or twice had to dissect off the ureter from the sac, but undoubtedly the greatest difficulty is with the intestines, and several times I have injured them, sometimes so badly that I had to resect the gut. If one can satisfy oneself that there is only one loop of the bowel involved in the adhesions it is almost better, if the adhesions are extremely intimate, to clamp off the loop of bowel and remove the adherent piece of bowel along with the uterus, tubes, and ovaries. That, however, is often not possible, and so one must generally plod on with patience and separate off the bowel as carefully as possible, attacking it from all sides—sometimes from below, sometimes from the side, and sometimes from above. After the uterus and tubes have been removed the bowel involved in the adhesions should be carefully examined, and if there is any tear in the lumen of the gut that should be repaired in the ordinary way.

Here is a recent grave case of pyosalpinx upon which I operated:—

A married woman, aged 28 years, was admitted to my ward in the Western Infirmary on Jan. 19th on account of severe hæmorrhage and abdominal pain. These symptoms had been present for five months; prior to that time her menstruation was fairly regular, although she had suffered from premenstrual pain for many years. She had no family. Shortly after her marriage she had a severe cystitis. Upon bimanual examination the enlarged uterus was found retroverted and adherent to two elastic swellings which could be defined behind and to the sides of the uterus. The condition was diagnosed as double pyosalpinx. On Jan. 31st I opened the abdomen and found omentum, bowel, tubes, ovaries, and uterus all matted together in the lower part of the abdomen and pelvis. Having tied off a piece of omentum and separated some of the bowel adherent to the uterus and left appendages, I was able to get down the left side of the uterus and tie off its attachments. I then cut across the cervix and working up from below and from above separated the right appendages without bursting the pyosalpinx. Having tied off the uterus

and ovarian vessels I removed the uterus and both tubes. I then found that the appendix was involved in the inflammatory process and so removed it. I now examined very carefully the separated bowel, which I found to be intact. Finding, however, that the whole of the cæcum was very much damaged indeed I was afraid to leave it, and so I divided the small intestine just outside the ileo-cæcal valve and closed both ends of the gut by purse-string and Lembert sutures. I then performed a lateral anastomosis between the ileum and the middle of the ascending colon. I then divided the colon, closed the upper end, and removed the cæcum. I finally inserted a cigarette drain, bringing the end out through the vagina. I also packed the lower abdominal and pelvic cavity with iodoform gauze.

The patient was naturally extremely collapsed after the operation, which lasted two and a quarter hours. She soon rallied, however, with continuous saline rectal infusion. About ten days after the operation fæces began to come by the vagina in considerable amount, but I felt sure this was simply from a fistula in the rectum along the track of my rubber drain. This proved to be correct as there are now practically no fæces coming by the vagina, and the bowels are moving satisfactorily with the aid of mild purgatives.

Now I feel that if I had chanced it in this case and left the badly damaged loop of bowel the result would almost certainly have been unsatisfactory. It is of the greatest importance that the injured bowel should be dealt with in a thoroughly surgical manner. It is folly to leave a very much damaged loop of bowel.

But besides removing the uterus, ovaries, and tubes, the appendix should also be dealt with. In the cases that I have had I have found the appendix involved on many occasions, and I have removed the appendix many times. This part of the operation is usually not very difficult, as in most of the cases the appendix is only secondarily involved and can be separated from the adhesions. I need not, of course, say that occasionally the removal of the appendix is a matter of extreme difficulty.

Having removed the inflamed mass of uterus and tubes and the appendix, and having repaired or resected the bowel if it is very extensively damaged, the abdomen is closed. Upon a few occasions I have drained through the vagina, and always by means of a rubber tube surrounded by gauze. I would not, however, be dogmatic on this point; I have sometimes been a little doubtful about the advantage of draining in such cases. All the vessels are tied with catgut; the abdominal wound is stitched in layers with catgut and silkworm gut.

Naturally the operation is one of considerable length. In the last case I referred to, where, in addition to removing the uterus and pus tubes, I removed the appendix and resected the bowel, the operation lasted two and a quarter hours. In such cases the patients, as a rule, suffer from considerable shock, but the degree of shock depends not altogether upon the duration of the operation, but is influenced very largely indeed by the manner in which the anæsthetic is administered. The ideal anæsthetist, who keeps his patient "under" with a minimum of ether or chloroform, is an absolutely invaluable assistant to the surgeon. Putting aside the surgeon's skill and dexterity and the ideal anæsthetist referred to, the next most valuable aid to the recovery of the patient in these extensive operations is a nurse who can superintend the administration of the continuous saline infusion. I am convinced of the great benefit of continuous saline rectal infusion after these difficult and prolonged operations. If all these precautions are carried out—if the uterus and tubes are removed without spilling any pus, if the injured gut is carefully resected when it has been seriously damaged, if the anæsthesia has been ideal, and if continuous saline infusion is employed—the mortality from these most difficult operations should be very low indeed.

I am very glad to be able to report that neither I nor my assistant, Dr. D. Dickie, have lost any case treated as I have described during the last two and a half years. I am well aware that a few gynæcological surgeons in this country—for example, Wilson of Birmingham—and some in other countries, have advocated a similar line of treatment. This paper is brought forward in support of the treatment, and I trust it will become more commonly practised—this radical operation for grave forms of pyosalpinx.

Glasgow.

# THE ASSOCIATION OF DUODENAL ULCER WITH APPENDICULAR DISEASE.

BY HERBERT J. PATERSON, M.A., M.C., M.B. CANTAB., F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE LONDON TEMPERANCE HOSPITAL.

SINCE Dr. W. J. Mayo called my attention to the frequency with which chronic appendicular disease is associated with gastric symptoms I have been struck with the frequency with which appendicular disease coexists with duodenal ulcer. I have found, in going over my notes for the last three years, that obvious appendicular disease was also present in 66 per cent. of the cases in which I have at operation found duodenal ulcer. In none of these cases was there any clinical reason to suppose the existence of disease of the appendix.

This association seems to me to be too frequent to be regarded as a mere coincidence and suggests that appendicitis may be one of the causes of duodenal ulcer. Why appendicular disease causes duodenal ulcer may not be easy to explain. There is a certain amount of evidence that gastric ulcers are toxic in origin, and I think it is quite possible that duodenal ulcer is the result of toxic absorption from the appendix or even from the large intestine.

It is now definitely established that appendicular disease does produce definite gastric symptoms, a condition for which I have suggested the term "appendicular gastralgia." Examination of the gastric mucosa in these cases often shows an extreme degree of erosion. It is possible that this condition is the prelude to definite ulceration of the stomach or duodenum. The sequence of events is this—appendicular disease; secondarily, erosion of the gastric mucosa; then superficial ulceration (the so-called "medical ulcer"); and later, a recognisable indurated ulcer.

I have had a patient under my care during the past year, the clinical details of whose case are very suggestive.

The patient was a lady, 42 years of age, sent to me by Dr. Stanley L. Box. Sixteen years before I saw her she had peritonitis, and was ill for months. A year later she had "ulceration of the bowels." Two years after that she began to suffer from gastritis, and a few years later she had hæmatemesis. In January, 1909, she was taken ill, suddenly, with violent vomiting, hæmatemesis, and melæna. Notwithstanding careful dietary and rest in bed, she did not lose her symptoms. She was seen by Dr. Soltau Fenwick, in consultation with Dr. Box, and a diagnosis of appendix trouble was made. I opened the abdomen, carefully explored the stomach and duodenum, and could find no evidence of gastric or duodenal ulcer. She had an enormously large appendix, measuring 3½ inches in circumference, and containing three large foul-smelling concretions. After the removal of the appendix (October, 1909) she was better, but still suffered from acidity. For some months she remained fairly well, and then—in May, 1910—became suddenly worse, and brought up about a pint of bright blood. In July she had several attacks of hæmatemesis and melæna, two of them severe. The pain and the hæmorrhage pointed so strongly to duodenal ulcer that in September, 1910, I again opened the abdomen, and on this occasion found a duodenal ulcer adherent to the liver. A posterior gastro-jejunostomy was performed, and the patient has been completely relieved of all her symptoms.

I have little doubt that in this case a superficial ulcer, which could not be felt, existed at the time of the first operation. The ulcer persisted, and in due time became thickened, so that at the second operation it was palpable as well as recognisable by sight.

Most of the patients suffering from appendicular gastralgia are cured by appendicectomy, but in from 10 to 12 per cent. of the cases, operation is not followed by complete relief. It is possible that the above case affords the explanation. An ulcer may already exist, although it cannot be felt by an external examination of the duodenum. This possibility raises the question whether in these cases a gastro-jejunostomy should be performed as well as appendicectomy. Personally, I am of the opinion that a gastro-jejunostomy should not be performed, unless there exists a definite ulcer which can be seen and felt. I quite admit that it is disappointing, both for the patient and for the surgeon,

if appendicectomy fails to relieve the gastric symptoms and further surgical treatment is necessitated; nevertheless, a 10 per cent. chance of a second operation being necessary does not justify an unnecessary operation in 90 per cent. of the cases.

Upper Wimpole-street, W.

## THE TREATMENT OF DISSEMINATED SCLEROSIS: A SUGGESTION.

BY E. FARQUHAR BUZZARD, M.D. OXON., F.R.C.P. LOND.,

OUT-PATIENT PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, AND TO ST. THOMAS'S HOSPITAL.

THE morbid anatomy of disseminated sclerosis is different from that of any other disease of the nervous system in the actual nature of the lesions by which it is characterised. Not only are the lesions patchy in their distribution, but each lesion presents, as its special feature, a destruction or alteration of the myelin within a well-defined area of the brain or spinal cord. This demyelinisation is often, if not always, followed by some neuroglial sclerosis, less frequently by changes in the axis cylinders which pass through the affected area.

From a clinical point of view the nature of the disease has always been obscure, but during recent years the theory that some toxic agent is responsible has steadily gained ground. From the clinical point of view disseminated sclerosis displays a strong resemblance to only one other disease of the central nervous system—i.e., cerebro-spinal syphilis. This resemblance is chiefly dependent upon the fact that both maladies are distinguished by paroxysmal attacks upon the cerebro-spinal axis occurring at intervals which may vary, according to circumstances and probably in accordance with general states of health, from a few weeks to many years. Recovery from one attack, even if some residual loss of function is the rule, is always possible, perhaps probable; but the liability to recurrence, unless preventive steps are taken in the case of the syphilitic disease, is generally recognised by all medical men.

Recent advances in our knowledge of syphilis tend to show that, having once gained access to the body, the treponema pallidum can be, as it were, stored away for indefinite periods, and yet can maintain the power of attacking one part or another of its host when a suitable occasion presents itself. For the moment it is of little importance to discuss the locality of its hiding-place. Adequate anti-syphilitic treatment will, in the majority of cases, suffice to prevent the occurrence of these tertiary outbreaks.

All attempts to discover a bacterial agent responsible for disseminated sclerosis have failed, just as failure dogged the footsteps of those who for many years sought the syphilitic germ by ordinary bacteriological methods.

The resemblance between cerebro-spinal syphilis and disseminated sclerosis has led me, during the last year or two, to suspect that the latter disease may be caused by some organism belonging to the same class as that of the treponema. The fact that this class of organism is best combated by mercury or arsenic induced me to commence the tedious experiment of treating a few selected cases of disseminated sclerosis by repeated courses, or nearly continuous administration, of arsenic, on the same principle as that which makes the repeated administration of mercury the only effective method of preventing attacks of cerebro-spinal syphilis in syphilised persons. The experiment is tedious, because in the natural history of disseminated sclerosis remissions are frequent and often prolonged, so that observations on many cases over many years would be necessary to establish the value or uselessness of this measure. So far as my experiment has gone there is nothing to show that it is useless, but I should be very sorry to claim any success on the material at present available.

The advent of Ehrlich's "606" preparation to some extent alters the situation. If the use of this preparation is to prove a method of permanently eradicating syphilis after infection, and if there is any basis of truth in the theory I have put forward concerning the pathogenesis of disseminated sclerosis, it might well be that what is efficient in the one case might prove equally so in the other. The difficulty of inducing patients to persevere with the continuous administration of a drug and the difficulty of knowing how far one's orders have been conscientiously obeyed would be overcome by substituting one or two "intensive" injections for years of medicine-taking. The fact that much time must elapse before the method of treatment can be thoroughly tested induces me to publish this suggestion now in the hope that others besides myself may see their way to try Ehrlich's preparation in suitable cases of disseminated sclerosis as soon as the experimental stage in its employment has been completed.

It is justifiable, even on the slender grounds I have offered, to try a therapeutic measure which may possibly be of service in influencing a disease so intractable as disseminated sclerosis, and it is interesting to note that nearly all observers are agreed in regarding arsenic as one of the most useful drugs in the palliative treatment of that disease. So far as I am aware, the use of arsenic in the manner I have described and for the reasons which I have ventured to advance has not yet been advocated, and I should certainly have hesitated in doing so now had not the remarkable results of Ehrlich's discovery in the treatment of syphilis made the means of putting my theory to a practical test so much more simple.

## TORSION OF THE LEFT BROAD LIGAMENT AND FALLOPIAN TUBE IN A CHILD.

BY M. A. CASSIDY, M.A., M.D., B.C. CANTAB., M.R.C.P. LOND.,

LATE RESIDENT ASSISTANT PHYSICIAN TO ST. THOMAS'S HOSPITAL;

AND

L. E. C. NORBURY, M.B., B.S. LOND., F.R.C.S. ENG.,

RESIDENT ASSISTANT SURGEON TO ST. THOMAS'S HOSPITAL.

ON Feb. 20th, 1910, a girl, aged 11 years, was admitted to St. Thomas's Hospital with the following history. Six days previously, while returning home from school, she was suddenly seized with acute abdominal pain associated with vomiting. She was so ill that she was carried to the nearest house, whence she was sent home later. She had been in bed since, suffering from severe abdominal pain, which was at first paroxysmal, but subsequently continuous. The pain was confined to the lower abdomen, and was worse on the left side than on the right. There was a little vomiting on the second day of her illness, but none afterwards. Both micturition and defæcation were painful. The bowels had acted twice on the day of admission and once on the previous day; no blood was passed either per rectum or per vaginam.

Further inquiry elicited the information that some three or four months previously the child had suffered from somewhat similar symptoms; on this occasion also the pain was situated in the left lower quadrant of the abdomen, and it was sufficiently severe to make her roll about in bed and scream. The onset was sudden and associated with collapse and vomiting. This first attack, however, lasted only one day, and between the two attacks she had been perfectly well and free from any abdominal pain.

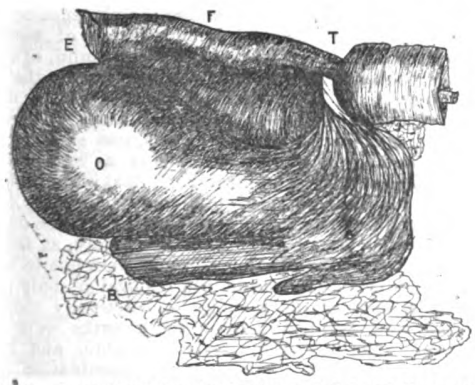
*State on admission.*—The child looked ill: the expression was anxious, and the eyes were sunken. The temperature was 100·6° F., the pulse 120, and respirations 30 per minute. The tongue was moist and but slightly furred. There was no abdominal distension nor retraction, but the respiratory movements were confined to the epigastrium, the lower half of the abdominal wall being quite motionless. No peristalsis was seen. The percussion note was everywhere resonant, and the liver dulness was normal. Palpation revealed great tenderness all over the lower half of the abdomen; this tenderness was most intense in the hypogastric and left iliac regions, where also there was definite cutaneous hyperæsthesia. The lower segments of both recti were rigid, but elsewhere the abdominal wall was flaccid. Per rectum a tender, œdematous mass was felt in Douglas's pouch, a little to the left of the middle line. The urine was normal and there was no evidence of any intra-thoracic disease.

The history and state were considered to be suggestive of a leaking pelvic abscess, probably appendicular in origin;

the very acute and apparently colicky nature of both the present and the previous illness were commented on as being an unusual feature, but one to which no great importance was to be attached, in the entire absence of any other symptoms or signs of intestinal obstruction.

Shortly after admission the abdomen was opened by one of us, under chloroform-oxygen anæsthesia, through the lower segment of the right rectus muscle, one inch from the middle line. On incising the peritoneum no free fluid or peritonitis was found, and the intestines appeared to be normal. There were some old adhesions round the tip of the appendix, but no recent inflammation. On further investigation some blood-stained fluid was found in the pelvic cavity, which was next explored. The uterus and the right Fallopian tube and ovary were normal in appearance; in the pouch of Douglas, however, a large, chocolate-coloured mass was found, which proved to be the strangulated left ovary, with the corresponding broad ligament and Fallopian tube twisted several times. The patient having been placed in the Trendelenburg position, the incision was prolonged downwards and the intestines were packed off by abdominal pads. The attachment of the broad ligament to the pelvic wall was divided, and the whole mass was with some difficulty extracted from Douglas's pouch and brought into the wound. The broad ligament was clamped close to the uterus and ligatured with silk in three portions, and the Fallopian tube and ovary were removed. After the divided edges of the broad ligament had been united by silk sutures, the pelvis was dry-sponged and a considerable amount of blood clot was taken out. The abdominal incision was sutured in layers, silk being used for the peritoneum and rectus sheath, and salmon gut for the skin. Convalescence was uneventful; the wound healed by first intention, stitches were removed on the seventh day, the child got up on the twelfth day, and was discharged on the sixteenth day.

On examination of the parts removed it was found that



Sketch of specimen showing torsion of left broad ligament and Fallopian tube. E, Fimbriated end of tube. F, Fallopian tube. T, Seat of torsion. O, Ovary. B, Blood-clot adherent to Douglas's pouch.

the broad ligament and Fallopian tube had undergone several complete twists in a clockwise direction close to their uterine attachment. The tube and ovary were black, and the broad ligament was infiltrated with blood clot. A large piece of friable blood clot was attached to that portion of the mass which had been adherent to the pelvic wall. The ovary was four inches long, an inch and a half wide (from above down), and an inch thick (from behind forwards). A microscopical examination, kindly made for us by Dr. Leonard S. Dudgeon, showed only extreme vascular engorgement of the ovary. There was no evidence of disease of the ovary, apart from the results of strangulation.

We have ventured to put this case on record on account of the extreme rarity of the condition found. Torsion of the pedicle of ovarian tumours in children is, of course, not uncommon; in fact, the ovarian tumours of childhood appear to be very liable to this accident. Damianos[1] refers to 14 cases of torsion of the uterine adnexa in inguinal herniæ of young children; and Morrel[2] reports a case of torsion of the left Fallopian tube in a woman, aged 32 years, without any concomitant strangulation of the ovary. Haultain[3] has published a case of apparently chronic torsion of the Fallopian tube and broad ligament, with infarction of the ovary; the operation was performed on account of metrorrhagia of 18 months' duration, and there were no acute symptoms. We have been unable to find in the literature any instance of acute strangulation of a healthy and normally situated tube and ovary.

We are much indebted to Dr. T. D. Acland and Mr. H. Betham Robinson for permission to publish this case, and to Mr. W. Victor Corbett for his sketch of the parts removed, which is reproduced here.

## MASSIVE INFARCTION OF THE RENAL CORTEX.

BY JAMES A. TORRENS, M.B., B.S. LOND., M.R.C.P. LOND.,
MEDICAL REGISTRAR TO ST. GEORGE'S HOSPITAL.

FROM the rarity of this condition the following case seems to be worthy of record.

A woman, aged 29 years, was admitted to St. George's Hospital on August 21st, 1910, under Dr. Arthur Latham's care with the history that seven days previously she had had a miscarriage at the fourth month, followed immediately by complete suppression of urine and two days later by obstinate vomiting which persisted throughout the illness. The patient had always been healthy, except that her first confinement was followed by puerperal septicæmia. Her subsequent children were born prematurely at six and seven months respectively.

On admission the patient was found to be a stout woman; her face was flushed, and her expression bright and eager. The pupils reacted well, were equal, and moderately dilated, and the tongue was moist and clean. She was mentally alert and intelligent, had no headache, and indeed said that she felt quite well except for the discomfort caused by vomiting. There were no twitchings or convulsions; the reflexes were natural and the fundi did not show any change. The temperature was 99° F., the pulse 112 (not high tension), and the respirations were 28. Examination of the thorax and abdomen did not reveal anything abnormal, while an X ray photograph was negative. A catheter was passed and 1 cubic centimetre of urine containing pus and red blood cells was withdrawn. The vomiting persisted, and 24 hours after admission the patient died somewhat suddenly after complaining that she felt sick and faint.

At the necropsy, made 23 hours after death, the following notes were made:—"The body is that of a well-nourished woman inclined to obesity. There is a very slight degree of œdema of the ankles. *Thorax.*—No ascites. The abdominal and pelvic viscera are healthy, with the following exceptions: *Kidneys.*—8 ounces each; the capsules str readily, exposing a smooth mottled red and yellow surface. On section the entire cortex is pale buff in colour, and is surrounded by a bright red line of hyperæmic reaction; the pyramids are dusky red and stand out distinctly in contrast to the pallid cortex. The condition appears to be massive infarction of the entire renal cortex. *Bladder.*—Contracted and empty save for 1 cubic centimetre of muco-pus; no cystitis. *Uterus.*—Measures 5 inches by 4 inches by 4½ inches and contains several ounces of decomposing blood-clot. *Vessels.*—The ovarian and renal veins are thrombosed throughout (the right renal and ovarian veins open simultaneously into the inferior vena cava). The clot, which does not appear septic, is partly canalised in places, and has extended as a tapering prolongation for about three inches down the inferior vena cava, but has not obstructed the lumen of that vessel. The renal arteries do not show any atheroma or endarteritis. Microscopically, the kidneys show general infarction of the cortex. There is hæmorrhage into the tubules and glomeruli, but no evidence of endarteritis; the veins, however, appear thrombosed."

The history of this case and the naked-eye appearance of the kidneys are practically identical with those described by

[3] Journal of Obstetrics and Gynæcology, vol. viii., p. 25.

Bradford and Lawrence,[1] but in their case the condition was ascribed to a definite and selective endarteritis obliterans of the renal arteries. Herringham and Griffith[2] describe a case that is clinically similar but in which, while there was no endarteritis obliterans, there was a definite increase of interstitial tissue throughout the kidneys. Parkes Weber,[3] in describing what appears to be a somewhat different type of case, regards the fault as being a primary defect in the tubal epithelium. In the cases quoted by Herringham and by Bradford, as well as in the present one, the anuria dated from childbirth or miscarriage, but so far as I have been able to ascertain, this is the first case in which the lesion has been shown to be directly attributable to thrombosis of the renal veins, though it has been demonstrated by physiological experiment that obstruction to the renal vein will produce a condition of typical infarction.[4]

I am indebted to Dr. Latham for permission to publish this case.

## ROYAL SOCIETY OF MEDICINE.

### SURGICAL SECTION.

*Cancer of the Rectum.*

A MEETING of this section was held on Jan. 10th, Mr. RICKMAN J. GODLEE, the President, being in the chair.

Dr. F. WOOD JONES, speaking on the anatomy of the rectum, pointed out the advisability of recognising Houston's first fold as a really useful indication to mark out the limits of the rectum.

Mr. F. SWINFORD EDWARDS said he would briefly state his own views on the present position of the operative measures necessary for the removal of a rectal cancer and his experience of the various methods he had employed. His chief object was to enter a protest against the performance of an unnecessarily severe operation, with a heavy mortality, for cases of cancer attended with but little risk to life, and which, moreover, entailed no crippling of the patient. All forms of treatment other than operative, whether by radium, X rays, high-frequency currents, trypsin and other digestive ferments, had, and he thought it was generally admitted, proved unavailing. Nowadays the position of the growth—namely, its distance from the anus—was no bar to extirpation. The only real bar to a successful operation was the fact that the growth was no longer confined to the bowel but had become adherent to neighbouring parts, whilst the lymphatics were infected. Another condition which quite barred any attempt at removal was metastasis in the liver, often not discovered until the abdomen had been opened, either for exploration of the growth or for the purpose of forming an artificial anus. In considering the best method to employ for removing the disease due regard must be paid to the immediate mortality of any given operation, the risk of recurrence, and the amount of crippling, if any, likely to follow the operation. Mr. Ernest Miles had advocated a very extensive proceeding, which he called the radical abdomino-perineal operation, for all malignant growths of the rectum and pelvic colon no matter how small they might be or where placed. That operation consisted in the formation of an iliac anus with the entire removal of the rest of the sigmoid colon, the rectum with the soft parts adjacent thereto, and the anus. He stated that his reason for advocating that extensive operation in all cases of rectal cancer was the great frequency of recurrence which followed his perineal operations, under which heading he included parasacral excision with end-to-end anastomosis. Out of 58 operations there were 54 recurrences. Mr. Edwards sympathised with Mr. Miles in the unfortunate results attending his perineal and sacral excisions, nor could he offer any explanation to account for them, unless it were that many of those cases were unfavourable for any operation, the disease having probably passed beyond the limits of the bowel at the time of the operation and had better have been left alone. Mr. Edwards had always held the opinion that all growths fixed anteriorly or laterally, even when involving only a part of the bowel circumference, were best left alone. If the meso-rectal glands and lymphatics were markedly enlarged and remained so, either after a preliminary colotomy or after rest in bed with frequent rectal douching, recurrence after operation was not improbable. It must be admitted that enlarged glands were often only inflammatory and not malignant. He had several times met with those glands when carrying out a parasacral excision and had been much disappointed on finding that he was unable to remove the entire chain. Some of those cases were alive and well to-day, having passed the three years' limit, a proof, he thought, that those glands were not cancerous. For some 10 or 12 years he had abandoned the old perineal operation excepting for cases of epithelioma of the anus, and in the majority of cases had performed the extirpation by the sacral or coccygeal route. He had not concerned himself with the preservation of a bone flap, as patients appeared to suffer no inconvenience from the loss of the coccyx and lower part of the sacrum. If the growth was extensive, involving the removal of, say, four inches or more of bowel, or if it extended so low down that end-to-end union was problematical, he advised a preliminary colotomy. If the anus had been preserved and the continuity of the bowel re-established, the artificial anus could be closed subsequently; but bearing in mind the chance of recurrence that might well be postponed for a year. When performing the colotomy the hand should be passed into the abdomen for the purpose not only of defining the limits of the growth, but also of exploring the liver and ascertaining the presence or otherwise of enlarged glands and lymphatics or of secondary growths elsewhere. The existence of these would, of course, negative any attempt at excision. Extirpation by the sacro-coccygeal route he had carried out 81 times with 4 deaths, or an immediate mortality of 5 per cent. There was recurrence in 22 cases. Hospital cases, lost sight of, numbered 14. Forty-one cases were well as far as was known; of those, one was still in a surgical home making a rapid convalescence. He thought that a preliminary colotomy seemed to offer some bar to recurrence. When recurrence did take place it was with one exception *in situ*—namely, at the level of the bowel section. Partial excisions were not to be condemned. By partial he meant the removal of only part of the circumference of the rectum. Theoretically they were unsurgical, and in all the cases the growths were small, none larger than a florin, freely moveable, and limited to the post-rectal wall. Microscopical examination proved them all to be malignant adenomata. In one case, operated upon four years ago, he removed in addition four enlarged glands, in two of which metastatic deposits were found. That lady was now in perfect (rectal) health and by a digital examination it was almost impossible to say that she had undergone any operation. Most of the cases of recurrence had been either in young subjects or in cases where the section of the bowel was perilously near the disease—namely, the specimen when removed did not show an inch of healthy mucous membrane above and below the growth. In conclusion he expressed the opinion that rectal cancer in persons of 45 and over was not prone to recur if removed sufficiently freely, but in the young it was very malignant and was likely to recur unless removed at a very early stage. Cases of cancer of the sigmoid colon were very favourable ones for operation by the abdominal route, with end-to-end union, unless obstruction was present, when a temporary colotomy should be the rule. Subsequent excision with intestinal anastomosis could then be carried out. In those cases he had had excellent results. For growths involving the upper rectum and pelvic colon an abdomino-perineal operation was necessary. Miles's amplification of it also had its field of usefulness for cases in which the disease had passed beyond the walls of the bowel and which otherwise should be considered inoperable. The radical abdomino-perineal operation entails an artificial anus, which, when necessary, was no great evil. Indeed, it

[4] Adami and Nicholls: The Principles of Pathology: Systemic Pathology, Feb. 27th, 1909, p. 42.

might be a positive advantage in preventing a tendency to recurrence. When the artificial anus was intended to be permanent he preferred hypogastric colostomy through the left rectus muscle to an iliac one, as he found it conferred a much larger measure of control. But where a subsequent abdominal section was purposed for an excision the iliac site was the better, for being placed farther out the abdominal wound was not so likely to be infected. To his mind the ideal operation for cancer of the rectum when situated between the fourth sacral vertebra above and a point 2 inches above the anus below was Bardenheuer's modification of Kraske's operation with end-to-end suture. It was true that a dorsal fistula would persist for a time, but that usually healed in from two to three months if the stricture at the line of union was kept dilated. He had always found contraction take place at that point with a very marked anterior spur. That in time practically disappeared if treated by dilatation, for which purpose he found nothing to equal Hegar's double curved metal dilators. In the face of his own results he could not agree with those surgeons who advocated a combined operation for all cases of rectal carcinoma, any more than he agreed with those who for a small and limited cancer of the breast would remove all but the ribs, and thus cripple the patient for life.

Mr. W. HARRISON CRIPPS said he agreed with what Mr. Swinford Edwards had said. It was almost exactly the same as what he had been saying for years. To consider the route by which cancer of the rectum should be removed was a secondary question; the most important point was, could the cancer be removed with advantage to the patient? The class of case that he considered suitable for removal of the cancer was one in which the growth was still confined to the rectum and had not extended beyond; to discover if the growth was confined in that manner it was necessary to find out by feeling whether it was fixed or not; if not fixed, then the disease could be removed with advantage to the patient. Mr. Harrison Cripps said it took him some time to learn when a growth was removeable or not. The chief consideration was whether the growth had gone through the walls of the rectum and extended to the neighbouring tissue. If that were the case his experience was that operation would not secure a permanently successful result. Mr. Harrison Cripps emphasised the importance when examining of making the examination of a rectal cancer under an anæsthetic. As regards recurrence, in most of his cases the cancer when it recurred was found in the tissue surrounding the part from which the growth had been removed. Concerning the method of operation he thought it was impossible to lay down precise rules. Turning to the question of the value of the operation, his view was that if there was any doubt as to whether a growth should be removed or not the benefit of the doubt should be given for the removal of the tumour. He believed a very large number of these cases of cancer of the rectum were curable if operated upon early, and appealed to practitioners to spend more time in studying the symptoms of the disease.

Sir FREDERICK S. EVE said that judged by the best clinical observation and by the percentage of permanent cure there was no doubt in his mind that Kraske's operation or the perineal type had not been sufficiently thorough. In regard to cure every surgeon was aware that a three years' limit was far too small. There were plenty of cases of cancer in which recurrence occurred after ten years. He had seen a melanotic cancer recur after 20 years. It was true that cancer, if it recurred did so soon, but there were many cases in which it recurred late, and he had seen two cases in which recurrence took place after five years' freedom from the disease. It was clear that Kraske's or the perineal method of operation could not be trusted to obtain a permanent cure, and he had come to the conclusion that the operation which filled the most important position, namely, a permanent cure, or the probability of it, at a low mortality risk, was the abdomino-perineal operation combined with a permanent colostomy. Although he advocated the abdomino-perineal operation and colostomy for the greater number of cases of carcinoma of the rectum, he recognised that the disease, if it only affected the anal canal, could be attacked from the perineum.

Mr. H. F. WATERHOUSE emphasized the importance of preliminary preparation. When intestinal obstruction the result of cancer of the rectum was present an inguinal colotomy must be immediately performed, and all attempts at radical cure abandoned for some days. Failure to recognise the importance of that rule had to his knowledge proved disastrous. Even in cases in which no obstruction had occurred and in which daily or more frequent evacuations of the bowel took place it was, in his opinion, essential to attempt to diminish as far as possible the septicity of the bowel. He was accustomed to administer castor oil on the sixth and fifth days preceding the operation. During the four days prior to operation the patient was given beta naphthol and salol, gr. v. of each in a cachet four times daily, and his food was restricted to milk and meat extracts. Eight hours prior to the operation half a grain of opium was given in pill form, and half an hour prior to the administration of the anæsthetic a hypodermic injection of ⅓rd grain of morphine hydrochlorate and 1-80th grain of atropine sulphate was administered. The rectum was washed out twice daily for two days, and again on the operating table with a 1 in 2000 solution of permanganate of potassium. The bowels after that rarely acted until the third, fourth, or fifth day, and a considerable number of incisions (parasacral) healed completely, or more commonly largely by primary union. He was a strong adherent of the parasacral method for which they were indebted to Kraske and Kocher. In his opinion it was the method of choice in almost every case of cancer of the rectum in which radical treatment was justifiable. He was in the habit of making use of that method in practically all the cases that came under his care. He had no doubt but that division of the sacrum markedly increased the shock of the operation and that the existence of a bone wound in a cavity likely to become septic was a very real danger. Even in cases of anal cancer he had long abandoned perineal excision. In such cases admirable access was obtained by the parasacral incision. Operating thus from above downwards was a far less sanguinary procedure than the method of perineal excision, for the reason that the blood-vessels could easily be clamped before division. If the anus were sutured or plugged with gauze at the commencement of the operation the diseased part could readily be pushed downwards outside the anal orifice, and, being there retained by an assistant, the parasacral incision was sutured before the protrusion was amputated. In that way union of the parasacral wound by first intention might almost always be obtained, as no fouling of the wound, hands, or instruments should take place. He was fully aware, however, that the great question they were called upon to discuss, and if possible to settle, was what was the best method of procedure in cases of cancer involving the first and second segments of the rectum of their student days or what should now be called the lower end of the pelvic colon and the rectum proper. Was the operation of the future to be a combined abdomino-perineal or abdomino-anal or some modification of the parasacral method of Kraske and Kocher? His vote was decidedly for the latter. He admitted that the combined abdominal methods appeared at first sight very attractive. They seemed in accord with the modern doctrine of freely removing all possibly infected glands, and he gave the method a fair trial, but he had, however, for all cases which could properly be called rectal cancers practically abandoned it. Among the reasons for his decision the chief was the difference in the mortality of the two methods. So far as he was able to judge the mortality of the combined abdominal method was not less than 30 per cent. and probably more. That of the parasacral method was, he believed, not more than 5 per cent. Adherents of the more serious operation must surely submit reasons more cogent than any he had hitherto heard before they could expect surgeons to abandon the far safer parasacral method. The reasons for the greater mortality of the former method were not far to seek. It was a question of two extensive incisions instead of one, of an operation of much longer duration—a matter of great moment in patients exhausted by pain and sleeplessness, not to mention septic absorption from the cancerous growth. The secret of success was free division of the peritoneal attachments of the bowel and free division of all bands connecting the posterior surface of the rectum with the sacrum. The amount of mobility of the bowel after free division of the peritoneal reflection was a revelation to those who practised that manœuvre for the first time. End-to-end union of the bowel segments had afforded him satisfactory results in many cases, though he was bound to confess that in the majority of instances leakage

had occurred on the posterior aspect of the line of union. As to the various combined abdominal methods, he stated that the more he saw of them the less he liked them. They were, in his opinion, far too severe, certainly for the ordinary run of cases of operable rectal cancer. They were double operations and entailed a severe strain upon debilitated patients. In not a few cases in which he had commenced the operation *viâ* the abdominal route and found a cancer at or just above the pelvic brim he had deemed it safer to perform a colotomy by bringing the upper end of the bowel out through the abdominal incision and closing, after excision of the cancer, the lower segment, without making any attempt to perform an end-to-end anastomosis or to bring the upper segment down to the anal margin. He was convinced that that was a far safer operation than any of the combined methods, and that the disadvantages of an inguinal anus were much exaggerated. He referred to the advantage of the removal of the infected glands which lay along the iliac vessels. In his opinion, when the disease had spread to those glands the prospects of radical cure were practically *nil*. He thought the glands that in all cases called for removal were those between the rectum and the anterior surface of the sacrum, and there could be no question that those could be far more radically removed by the parasacral incision than by the abdominal method.

## MEDICAL SOCIETY OF LONDON.

*Some Ocular and Visual Conditions in Medical Cases.*

A MEETING of this society was held on Monday, Jan. 9th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. JAMES TAYLOR, in the course of a paper on Some Ocular and Visual Conditions in Medical Cases, considered the subject in five sections: (1) Conditions of the pupil; (2) conditions of ophthalmoplegia externa; (3) changes in the optic nerve; (4) retinal changes; and (5) hemianopia. In the pupil conditions inequality was not necessarily of grave significance. The Argyll Robertson pupil he referred to in its association with syphilis; it was said also to occur with lesions in the vicinity of the third ventricle. Dr. Taylor also mentioned its association with definite signs of tabes dorsalis, general paralysis of the insane, with paraplegic or hemiplegic symptoms, the results of syphilitic disease of vessels, and with wasting about the shoulder girdle, the result of syphilitic cervical pachymeningitis. It might also occur as an isolated phenomenon, and the case was mentioned of a man who had been under observation for 16 years with merely neurasthenic symptoms. He had recently developed deafness of both ears probably of syphilitic origin. In speaking of ophthalmoplegia externa isolated sixth nerve paralysis was alluded to, and the question was raised whether it ever resulted simply from neuritis due to exposure to cold. He pointed out that he had never met with it associated with seventh-nerve affection (Bell's paralysis). The sixth nerve frequently suffered from accident—probably because of its prolonged and exposed course—e.g., in fracture of the base. Third-nerve paralysis, isolated, was usually the result of syphilis, sometimes in tabes, sometimes as a precursor of general paralysis. Both those nerves might suffer in general brain conditions—e.g., tumour, meningitis, &c.—and from toxic conditions such as diphtheria. In myasthenia gravis ocular palsies were one of the chief and early signs and varied much in intensity from time to time. Third-nerve paralysis also occurred in the condition known as migraine ophthalmoplégique, probably as a result of an actual lesion of the nerve. He then referred to the occurrence of optic atrophy in tabes dorsalis, and demurred to the statement that it occurred in the pre-ataxic stage of tabes, because in some cases of tabetic optic atrophy no ataxy developed. It also occurred in general paralysis of the insane, not infrequently many years before the mental symptoms were present. The optic atrophy of disseminated sclerosis was also discussed. Optic atrophy also occurred in lesions at the chiasma, optic neuritis in such conditions being extremely rare. Optic neuritis occurred most commonly as a result of intracranial tumour. In spite of assertions to the contrary, it was frequently an early sign, and the impairment of vision which it caused might be the first thing to excite the attention of the patient. In four years at Moorfields Dr. Taylor had had referred to him no less than 20 patients with optic neuritis who went to Moorfields before seeking advice elsewhere. Optic neuritis also occurred occasionally in disseminated sclerosis. It also was said to occur in anæmia and as a result of other toxic conditions such as influenza. Neuroretinitis occurred in glycosuria and albuminuria. The condition of retinal thrombosis and its symptoms were referred to and also the absence in many cases of any signs of associated visual disease. Occasionally cardiac hypertrophy was present. In the other cases a local arteriosclerosis was probably the cause, and the long subsequent life of many who had suffered from retinal thrombosis would seem to indicate that it did not necessarily imply a serious general condition. Embolism of the central artery of the retina was also referred to and its occasional occurrence—namely, after diphtheria—without any recognisable sign of heart disease. Homonymous hemianopia, although usually occurring with hemiplegia, permanent or temporary, slight or severe, might be an isolated phenomenon, the result of vascular blocking, frequently the result of syphilitic endarteritis. Bitemporal hemianopia was always the result of a lesion at the chiasma, occasionally associated with signs of acromegaly, frequently not.

Mr. PERCY FLEMMING read a paper on Some Cases of Medical Interest met with in Ophthalmic Work. He said that myopia in the great majority of cases was of course due to the axis of the eyeball being too long—axial myopia, and the onset of such myopia occurred in youth. A rarer cause of myopia was a change in the refractive index of the lens—index myopia. Such a change in the refractive index might be accompanied by fine changes in the lens visible with the ophthalmoscope, but in a minority of cases no such visible alteration in the lens accompanied the change in refraction. The onset of myopia in a patient over 40 was a striking event. Such patients said that whereas they could formerly see distant objects quite clearly, now everything a few yards away was blurred, and further, that whereas glasses were formerly needed for reading, now print could be read without their aid. An ophthalmoscopic examination usually showed fine lens opacities, but in a few of those cases the lenses were clear. In the latter group of cases examination of the urine would usually show the presence of sugar. Another point in connexion with diabetes to which he wished to refer was the occurrence of retro-ocular neuritis. The characteristic feature of retro-ocular neuritis was a loss of vision with little or no fundus change but with a definite central scotoma for red or white. Diabetes was recognised as a cause of retro-ocular neuritis, but a much more common one was tobacco, or tobacco in combination with alcohol. Although diabetes might produce typical retro-ocular neuritis apart altogether from tobacco, yet those cases were more often seen when the patient was a smoker, although the smoking might not be excessive. In such cases, if the tobacco be omitted improvement in vision usually occurred, but he had usually found the patients refuse to give up their smoking; they were fairly miserable from the diabetes, and they deliberately preferred the solace of their pipe to the prospect of improved vision. That being so, he should like to make the suggestion that those who had the care of diabetics in the early stages should warn them of the possible injurious effect of tobacco, and advise them to give up smoking. In patients over 45 one frequently met with a symptom which Mr. Flemming called morning ptosis. Such patients said that they had a difficulty in separating their lids in the morning, not because they were stuck together, but because they had no power to separate them, and they usually said that they had to push the lid up with their finger. No definite paralysis of any muscle was found, and although there might be a condition of ill-health or weakness present, yet the underlying cause in the majority of cases was the presence of uncorrected or insufficiently corrected presbyopia. The symptom might be taken as an indication of the need of glasses for near work, and with proper correction with spectacles the symptom would disappear. In the examples of that condition which had come before him the swelling had always been noticed first on waking. Another but quite different cause of difficulty in opening the eyes in the morning was the occurrence of angio-neurotic œdema. The swelling of the lids had always been noticed on waking, and had cleared up between 12 and 1 o'clock with what seemed to him rather extraordinary regularity. He had

nothing to say as to the cause of the condition, but some cases seemed to have been benefited by calcium lactate. Another and much more serious cause of transient œdema of the lids was the presence of a chronic frontal or ethmoidal sinus empyema. Cases of paralysis of the cervical sympathetic were fairly common, being due to various lesions in the neck and thorax, but the opposite condition, irritation of the sympathetic, which was often referred to in text-books as preceding paralytic phenomena, was in his experience very rare indeed. He had been on the look-out for such cases for years, and had only found one.

Mr. CHARLES HIGGENS pointed out the necessity for recognising the importance of the occurrence of double vision, and narrated two cases in which this was noticed in men over 60, one dying from a tumour of the brain and the other dying from cerebral softening. Mr. Higgens said that double vision was a symptom which did not have the significance attached to it that it should have amongst practitioners of medicine.

Mr. W. H. H. JESSOP pointed out that patients with ocular symptoms who did well under mercury need not necessarily be classed as syphilitics.

Dr. E. FARQUHAR BUZZARD narrated a case in which there was a condition of optic neuritis apparently due to the combination of alcohol and tobacco without any central scotoma.

Dr. WILFRED HARRIS pointed out how central scotoma may be the initial symptom of a pituitary tumour.

After Dr. THEODORE FISHER had spoken, Dr. C. O. HAWTHORNE commented on the fact that a retro-bulbar neuritis was now and then the first event in the development of disseminated sclerosis.

Dr. HERBERT FRENCH informed the meeting that a medical man in Queensland had put on record the fact that in a number of cases of children lead poisoning caused optic neuritis with paralysis of the sixth nerve.

Dr. H. A. DES VŒUX contended that unless ophthalmic surgeons examined the eyes of patients under atropine they would miss cases of headache due to conditions of the eye.

Mr. ERNEST CLARKE said that when cases of eye-strain were sent to the oculist of the old school for examination and report they might be returned to the practitioner with a statement that the headache was due to general conditions of the health. The only way to avoid that occurring was for the practitioner to insist on the report from the oculist being made after a cycloplegic examination.

After Dr. TAYLOR and Mr. FLEMMING had replied, the meeting concluded.

## LIVERPOOL MEDICAL INSTITUTION.

*Exercise Treatment of Knee Injuries.—Subphrenic Abscess.*

A MEETING of this institution was held on Jan. 5th, Dr. T. R. BRADSHAW, the President, being in the chair.

Mr. G. P. NEWBOLT showed a patient whom he had observed for many years and on whom he had performed many operations for Intestinal Fistulæ due to Tuberculous Peritonitis. A considerable amount of the intestine had now been resected from time to time and the abdominal wall had become closed.—Mr. R. W. MURRAY pointed out the danger of closing both ends of a piece of intestine.

Dr. W. H. BROAD read a note on the Exercise Treatment of Knee Injuries, and advocated a much earlier resort to massage than was usually practised, even when considerable synovitis was present. Many of his cases had been severe football injuries.

Mr. FRANK JEANS read a paper on Subphrenic Abscess. He had operated with complete success upon three cases recently, one being probably pneumococcal in origin, one following appendicitis, and one possibly arising from an infection of the kidney. Mr. Jeans said that the diagnosis was often difficult and pointed out the frequent obscurity of the etiology. Appendicitis and gastro-duodenal ulcers accounted for more cases than other abdominal causes. In diagnosis he had derived great benefit from radiography. The transpleural operation as far back as possible was the best and most usually applicable. He used a very large rubber drainage-tube, at least 1¼ inches in diameter. The use of the aspirating needle was condemned. He considered that it was of great importance to obtain a vaccine from the material removal since the case might become chronic.—A discussion arose concerning the use of the exploring needle. The general opinion of the surgeons was that this should not be used unless the patient was already prepared for an operation. The President and other physicians, however, maintained that its use in some cases was necessary.—Dr. JOHN HAY thought that œdema of the chest-wall was more likely to be present in subphrenic than in pleural collections of pus.—Dr. W. B. WARRINGTON considered that, excluding those cases in which the pleura had become infected, the important guide was the recognition of normal or exaggeration of normal signs above a somewhat sharply defined line of abnormal thoracic signs.—Mr. F. C. LARKIN said that he had several cases in which a left subphrenic abscess had arisen from infection due to œsophageal injuries from foreign bodies.

## MIDLAND MEDICAL SOCIETY.

*Exhibition of Cases.*

A MEETING of this society was held on Dec. 14th, 1910, at the Medical Institute, Edmund-street, Birmingham, Mr. W. F. HASLAM, the President, being in the chair.

Dr. A. STANLEY BARNES showed a typical case of Progressive Muscular Atrophy in a man aged 30 years. The atrophy was almost universal, but was most marked in the small muscles of the hands, the forearms, and in the shoulder girdle muscles. In the thigh and legs wasting to a moderate extent was present, but there was a considerable degree of spasticity with increase of the knee-jerks, ankle clonus, and extensor plantar reflex on both sides. The most exceptional feature of this case was that coincidently with onset of the muscle atrophy the patient developed epilepsy which was not of the Jacksonian type, and which persisted in spite of treatment throughout the nine months since the illness commenced.

Dr. A. DOUGLAS HEATH showed a female child, aged 2 years, with an eruption of Favus on the abdominal wall. The patch of eruption was circinate in shape and rather larger than a two-shilling piece, flattened in the centre and raised at the margins. On Dec. 2nd on the centre of the area and here and there on the raised margins were sulphur-yellow cups typical of favus. These had disappeared at the time the case was shown. Cultures taken from the yellow cups proved the fungus to be the achorion quinckeanum of Bodin, an uncommon variety of favus growing rapidly in white downy cultures. Another child, 8 years of age, and living in a house next door to the patient exhibited, had a red raised area on the outer side of one elbow with a well-defined favus cup in its centre. Dr. Heath had not seen this variety of favus before, all his previous cases having grown the achorion schoenleinii on culture, but a case had been shown before the Dermatological Section of the Royal Society of Medicine in October, 1908, by H. G. Adamson, which gave similar cultures.

Dr. HEATH also showed a case of Rodent Ulcer of the Nose in a woman aged 60 years. The disease had been present for six years, and for six months or longer had been ulcerated and covered by blood crusts. The ulcer was almost cured, having been treated by three exposures to pure radium bromide using a screen of lead foil and thin rubber. Each exposure had lasted for three-quarters of an hour and had been made at weekly intervals.

Mr. FRANK BARNES showed a case of Aneurysm of the Groin involving the Common Femoral and the Lower Part of the External Iliac Arteries treated by ligature of the external iliac by the transperitoneal route. The patient, a man, aged about 40 years, early in July last had received a blow in the groin from some tubes which he was carrying. He had pains in the groin, but did not complain of anything else until a month later, when he noticed a lump in the same place which grew rapidly larger during the next fortnight and caused him to seek advice. He was admitted to the hospital on Sept. 2nd and was operated upon on the 8th. His previous history included several years in the army, most of which he had spent in India. During that time he had had fever, and was warded for a month, and gonorrhœa, for which he was treated for a month, but never remembered having had syphilis or any sore at the time of his illness. The patient was placed in the Trendelenburg position, and the abdomen was opened half an inch to the right of the right linea semilunaris and the intestines packed off from the iliac fossa by means of

gauze sponges, leaving a clear view of the peritoneum covering the brim of the pelvis and right iliac fossa. The aneurysm was seen to extend about half an inch above Poupart's ligament. The peritoneum was opened half an inch above this in the line of the vessel, which was exposed and ligatured by a double ligature of kangaroo tendon applied separately according to the Ballance and Edmunds method, merely approximating the inner coats of the vessel. The peritoneum was sewn up over the artery with a small catgut suture and the abdomen closed in three layers with mass sutures through the whole wall. Pulsation ceased at once in the aneurysm. Return pulsation was noticed in the sac about the tenth day and then seemed to disappear in the course of the next few weeks. To-day, 14 weeks from the operation, the tumour is hard and is noticeably smaller; pulsation is to be felt both in the mass and in the apparently solid vessel for about two inches below Poupart's ligament, but only on careful palpation.

Mr. W. E. BENNETT showed a man, aged 52 years, suffering from Paresis of the Right Leg associated with Sciatica. The illness commenced in November, 1907, with an acute attack of sciatica on the right side, from which he recovered, and was able to work until July, 1910, when he had a recurrence of the pains in the right leg. On examination there was found to be a spastic contraction of all the muscles around the right hip-joint and those acting on the knee-joint. The muscles below the knee were flaccid and atrophied, and the patient was unable to raise his foot or to move his toes. Sensation was normal. All the muscles on the front of the leg reacted to faradism of medium strength. Those on the back of the leg did so very feebly to the very strongest faradic current. The patellar reflex was exaggerated, but all the other reflexes were normal. Babinski's sign was not present. The wasting of the muscles below the knee was considerable, the difference in the measurement round the calf of each side being 2½ inches.

Mr. B. J. WARD read notes on Four Cases after Resection of Gangrenous Intestine in Strangulated Hernia, giving details of the operation performed on each. End-to-end anastomosis after resection of the gangrenous intestine was effected by simple suturing. All four patients recovered and one was shown at the meeting.

Mr. A. W. NUTHALL exhibited a boy, aged 13 years, over whose right iliac crest was situated a large lymphangioma, the appearance of which agreed with a description given by Sir Jonathan Hutchinson and illustrated by him as lupus lymphaticus in his "Illustrations of Clinical Surgery." The main body of the nævus was a pear-shaped raised plaque three inches in length, and there were a number of isolated papillomatous outgrowths.

# Reviews and Notices of Books.

*A System of Syphilis.* Vol. VI. Edited by D'ARCY POWER, M.B. Oxon., F.R.C.S. Eng., and J. KEOGH MURPHY, M.C. Cantab., F.R.C.S. Eng. London: Henry Frowde and Hodder and Stoughton. 1910. Pp. 574. Price £2 2*s.* net per vol., or to subscribers £10 10*s.* net the set of six volumes.

IT is very fitting, as Sir Alfred Keogh points out in the preface to this volume, the sixth and last of the series, that in a work dealing with the subject of syphilis one volume should be devoted to a consideration of that disease as it affects the naval and military services. Not only is the early history of the disease closely bound up with the military history of the fifteenth century, but there is no disease, with the exception of malaria, which plays so important a part in the medical history of the army and the navy. Even at the present day the question as to the complete curability of syphilis still awaits settlement, and there can be no doubt that the soldier or sailor who has once suffered from the disease is no longer the man that he was. He is more likely to break down under the stress of service conditions or the hardships of war, and syphilis undoubtedly has a greater effect in lessening the physical efficiency of the soldier than any one of the infectious diseases.

In the present volume the history and epidemiology of syphilis in the more important armies is dealt with by Lieutenant-Colonel C. H. Melville, R.A.M.C. The charts given showing a steady fall in the admission rate for this complaint are most interesting and encouraging, and demonstrate, as Sir Alfred Keogh points out, the good results which have attended the observance of a higher ideal of conduct on the part of the rank and file of the army, and the ungrudging and persistent efforts of the officers of the Royal Army Medical Corps. That the latter have done much to advance our knowledge of the pathology and treatment of syphilis must be admitted by all workers in this branch of medicine, and the fact that a large number of the articles in this System are written by officers of this branch of the service is further proof, if any were needed.

In the second section of the volume Captain L. W. Harrison, R.A.M.C., describes the pathology and microbiology of syphilis as applied to the public services, and this section is followed by one by Major C. E. Pollock, R.A.M.C., on its clinical course and treatment in the army. Surgeon C. N. Fiske of the United States Navy contributes a chapter dealing with some noteworthy features of syphilis in the navy of the United States of America, and Fleet-Surgeon E. P. Mourilyan, R.N., and Staff-Surgeon Charles K. Bushe, R.N., deal with the epidemiology and treatment of syphilis in the British Navy. The concluding article in the book is a short one on the value of Justus's test in the diagnosis of syphilis by Staff-Surgeon W. P. Yetts, R.N.

The illustrations, as usual, are excellent, and the whole volume forms a worthy conclusion to the System of which it is a part. We must congratulate the editors on the termination of their work and the success with which they have carried it out.

*Memorials of 80 Years.* By JOHN BEDDOE, M.D. Edin., LL.D. Edin., F.R.S. Bristol: J. W. Arrowsmith. 1910. Pp. xi.–322. Price 7*s.* 6*d.* net.

THESE memories of 80 years are really memorials of the quiet life of one of the last members of that band of workers who raised the study of anthropology to a science in this country. The book tells in a pleasant and chatty manner of the years, all too quickly passed, in which a hobby became a serious pursuit, and led Dr. Beddoe to his present position as a recognised authority on anthropology, more especially in relation to the races of Great Britain.

A delicate child, born of an old yeoman stock in south Shropshire, his early life was spent at Bewdley, where he soon became familiar with the flowers and insects of the forest of Wyre. Destined for the law, his dyspeptic troubles led him to study physiological chemistry, whence by easy gradations his attention was turned to medicine. He entered at University College, and ultimately obtained a medical degree both at London and at Edinburgh. Inclined to roam, and having some influence, he was appointed to the civil hospital staff during the Crimean war, and was attached to the hospital of Scutari, having amongst his companions E. A. Parkes, George Rolleston, Holmes Coote, J. Whitaker Hulke, Carsten Holthouse, David Christison, and John Kirk. The life was to his taste; he learnt Turkish sufficiently to carry him through the country, and some of the most interesting passages in the book are those describing the pleasant excursions made in a district which has not even yet become hackneyed. The war being ended, Dr. Beddoe did not immediately settle in practice but made a tour of Europe to observe the colours of the eyes and hair in the inhabitants of the different countries through which he passed, with the occasional measurement of a skull when it was possible without giving offence. In 1857 he settled as a physician at Clifton, not, he himself says, a very fortunate choice of locality, because he

had as his competitors J. Addington Symonds, father of the author, and Ed. Long Fox. In Bristol Dr. Beddoe's life seems to have pursued the even tenour of its way familiar to all practitioners, varied by journeys to Ireland and Brittany, and diversified by attendance at meetings of the British Association. Increasing age brought a respite from work and allowed time for a journey to the Antipodes before Krakatoa had done its fell work of destroying the pink terraces, but giving us the after-glow which was so remarkable a feature of our sunsets in the eighth decade of the last century. This journey showed to Dr. Beddoe the youthfulness which is so striking a characteristic of many of our colonies. It was brought home to him somewhat as a shock, for he says: "I was asked to preside at a teetotal meeting and was a little surprised at its conclusion when a gentleman proposed a vote of thanks to 'our venerable friend in the chair.' I was fifty-nine, and though bald and grey had as yet no feeling of the approach of old age; but when I had spent a little more time in the colony I recognised that there was hardly a man over sixty in the whole of North Queensland."

The Welsh blood running in the veins of Dr. Beddoe must be held responsible for the curious vein of superstition, thinly veiled as "coincidence," which crops up two or three times in the narrative. Here and there, too, are occasional slips, as when Syme is given a title, Rolleston is described as a surgeon, and the name of Sir William Macewen is spelt incorrectly; but these are as nothing, and the interest of the book is great. The frontispiece represents Dr. Beddoe photographed as he stands in front of his house at Bradford-on-Avon.

---

*Human Anatomy for Art Students.* By Sir ALFRED D. FRIPP, K.C.V.O., C.B., M.B., M.S. Lond., F.R.C.S. Eng., Surgeon-in-Ordinary to H.M. the King, Surgeon to, and lately Lecturer upon Anatomy at, Guy's Hospital; and RALPH THOMPSON, M.B., Ch.M. Vict., F.R.C.S. Eng., Senior Demonstrator of Anatomy, Guy's Hospital. With drawings by INNES FRIPP, A.R.C.A. Lond., Life-Master, South London Technical Art School, City Guilds; and an Appendix on Comparative Anatomy by HARRY DIXON, M.S.B.S. With 151 illustrations. London: Seeley and Co., Limited. 1910. Pp. 296. Price 7*s.* 6*d.* net.

ALTHOUGH this book is written especially for students of art it is fair to say that there is much in it with which the average student of medicine would do well to have a better acquaintance; for the work possesses what so many so-called "human anatomies" utterly lack—an element of human nature introduced among the many structures of which the human body is composed. There is much sound art in the book, and much anatomy that is good and really human. The style of writing is familiar and easy, and we are glad to see that the customary rigid phraseology of descriptive anatomy is, for the most part, replaced by a much less stilted, but no less effective, style. It is not impossible that in places this change has been carried rather too far, and exception might be taken to the description of the skin as "smooth and moist, yet not messy."

The writing of the book has been ruled by strong common-sense and a keen observation, and such a section as that describing the development of the young child is obviously the outcome of personal and interested study. It is somewhat to be doubted, though, if any special adaptation is to be seen in the fitness of the ball of the infant thumb to furnish an air-tight plug for the infant mouth, or in the fitting of the groove between two fingers to the philtrum of the upper lip when a child sucks its fingers.

The illustrations by Mr. Innes Fripp are excellent, but the reversing of Fig. 66 makes it very confusing, and one or two minor imperfections may be noted. The pelves represented on p. 45 as respectively male and female show two rather obvious sex contradictions, for in the female the centrum of the first sacral vertebra appears to be as large absolutely, and relatively to the lateral masses, as in the male; also in the female the acetabula are as large as they are in the male. The drawings of surface anatomy are excellent, and a series of photographs of the nude goes to complete a human study of the form of the human body which is a useful work and a genuine addition to anatomical literature.

---

*Anæmia.* By Professor P. EHRLICH and Professor A. LAZARUS. Part I., Vol. I.: Normal and Pathological Histology of the Blood. Second edition. By Professor LAZARUS and Dr. O. NAEGELI. Translated from the German by H. W. ARMIT, M.R.C.S. Eng., L.R.C.P. Lond. London: Rebman, Limited. 1910. Pp. 218. Price 12*s.* 6*d.*

PRESSING obligations prevented Professor Ehrlich from taking part in the preparation of this second edition, and he therefore requested Dr. O. Naegeli to coöperate with Professor Lazarus.

The first chapter commences with a definition of anæmia. In its etymological sense this word deals with a blood the content of which is smaller than in health, but, as the authors point out, in practice all conditions in which a diminution of the hæmoglobin content is ascertainable must be regarded as anæmic. In the majority of cases, even if this diminution is not quite constant, oligæmia and oligocythæmia exist simultaneously in varying degrees. The most important methods of clinical hæmatology depend, directly or indirectly, on the recognition of these changes, and the rest of the chapter is occupied with a discussion of the methods employed for the examination of the blood.

The author deals next in an exhaustive manner with morphology and pathological histology, and so reaches perhaps the most important section of the book, which contains a detailed consideration of the white blood corpuscles. The normal histology and classification of the cells are first described and explained; then follow some remarks on the origin of the leucocytes and on the demonstration and significance of the cell granules. The wonderful application of intracellular chemistry which characterises Professor Ehrlich's work on the blood is well set forth. The authors of this work maintain that at the present time there is no longer any really earnest opposition to Ehrlich's doctrine of the specificity of the granulations and of the formed mature types of leucocytes. But an energetic struggle may still be said to exist with regard to the further question as to whether a sharp division should be drawn between the lymphatic and the myeloid systems, and between the cells which are derived from these two tissues. Professor Ehrlich has enunciated this dualistic doctrine as the most important result of his long-continued studies. We agree with the authors in the opinion that if all the arguments for and against the dualistic doctrine be reviewed, the past few years have brought some very important facts which speak in favour of this doctrine. Dr. Naegeli has been able to show by embryological investigations that the myeloid system first develops, and that much later, and as an absolutely separate phenomenon, the lymphatic system follows. He considers that in view of this fact the idea that myeloid tissue is only a more highly developed form of lymphatic tissue must be dismissed.

The subjects of leucocytosis and leukæmia are next considered at length, and many interesting points are discussed under these headings with the fulness that might be anticipated. A short description of the blood platelets concludes the work. It should be added that Mr. Armit has performed the task of rendering the ideas of the authors into a readable form of English with great success, and has thus enabled the medical profession in this country to have at its disposal a valuable work. It aims chiefly at defending

the manifold doctrines which Ehrlich has introduced into hæmatology, but these doctrines have earned a right to consideration.

---

*Spiritism and Insanity.* By Dr. MARCEL VIOLLET, Médecin des Asiles, Paris. (Library of Experimental Psychology and Metapsychism, edited by Dr. RAYMOND MEUNIER, Paris.) 1910. London: Swan Sonnenschein. Pp. 137. Price 2*s.* 6*d.* net.

THIS is the first of a series of little books addressed to the profession and to the educated public generally, whom it is hoped thus to keep acquainted with all the data acquired by contemporary science in the psychological and psychical domains. The collection will form a sort of synthetic essay on the *ensemble* of psychological questions and problems relating thereto.

Dr. Viollet begins by a description of various spiritualistic phenomena such as he has personally observed at *séances* by professional mediums; and, without passing any critical judgment on them, he emphasises the extent to which the "reality" or otherwise of these phenomena depends on the degree of "preparedness" of the members of the circle, each of whom is doing his utmost to get into *rapport* with the medium. Obviously the sole guarantee for the reality of the facts is the evidence of the senses of the spectators—a very inadequate basis on which to erect any interpretational hypothesis. Are we not accustomed to see the hallucinated insane not only believe in the reality of their hallucinations, but, moreover, rest persuaded that they are perceived by everybody? It is clear that there enter into the constitution of spiritualistic doctrines certain elements analogous to those entering into the constitution of certain forms of insanity; further than this Dr. Viollet does not go. The rest of the volume is taken up with an account of various clinical cases that have come under his own observation, in which frankly insane patients have suffered from mental symptoms that took birth in spiritualism, and these cases provide instructive reading. The anonymous translator of the book is to be complimented on his rendering of the original French.

---

*Gynecological Diagnosis.* By WALTER L. BURRAGE, A.M., M.D. Harv. With 207 text illustrations. London and New York: D. Appleton and Co. 1910. Pp. 656. Price 25*s.* net.

THIS clinical manual has been written for those who have not had an opportunity of studying gynæcology in special hospitals or clinics. Whether any manual, however good, will enable a practitioner in such conditions to become an expert in the diagnosis of gynæcological affections is a question to which our answer would be in the negative. Of all the branches of medicine gynæcology is essentially one which demands a considerable amount of clinical experience if any real skill is to be obtained in diagnosis. No doubt, however, many students will use this book in connexion with their practical work in the out-patient department or in the ward, and will thus learn a great deal which will enable them to make the best use of their clinical opportunities. It is an excellent manual, some parts being of especial interest, while on the whole the author has succeeded in his attempt to keep in the background those diseases which only appeal to the specialist and to give prominence to the commoner diseases of more importance to the general practitioner. The book contains chapters on the diagnosis of diseases of the bladder and rectum which should prove very useful, and also one on diseases of the breast, as the author considers these organs a part of the reproductive system, having intimate relations to the genital organs.

The first part of the book is concerned with the process of history-taking, the physical examination of the patient, and the special methods of investigation of the diseases of certain organs, such as the bladder and rectum. In the second part each disease is discussed in detail, a short account being given of the normal anatomy and physiology of each organ, and then the differential diagnosis is gone into. Frequent use is made of tabular statements in the differential diagnosis of different conditions, and a sufficient description is given of each disease to remind the reader of its main features. The author points out that the term endometritis is greatly misused, and that in the great majority of cases of hypertrophy of the endometrium, wrongly called endometritis, there is no evidence at all of any inflammation. Although apparently he agrees with this proper view of the matter, yet we find a certain amount of confusion on his writing, for a number of conditions, the result in reality of chronic congestion of the uterine mucosa, are described under the heading of chronic endometritis.

We regret, also, that the author does not attempt to answer the question as to what is an erosion, although from his description it is clear that his conception of an erosion is perfectly correct from the anatomical point of view, and we are glad to see that he does not label it by the misleading term "adenoma." But here again there is some confusion, for while Dr. Burrage says that "in an erosion there is no inflammatory action," yet on the next page the term endocervicitis is apparently used as signifying the condition of the cervix accompanying an erosion.

In discussing the effect of fibroid tumours upon neighbouring organs, we are told that they are a cause of abortion, and yet figures are quoted giving an abortion-rate of 12·7 per cent. and 15 per cent., as low as, and indeed probably lower than, the abortion-rate in all classes of pregnant women, which most authorities maintain is nearly 20 per cent. There is a good chapter upon the menopause.

The book is a useful compilation of its kind, and should prove helpful to students and practitioners. The index is full and the alphabetical index of the illustrations is a useful feature.

---

*Movable Kidney: Its Etiology, Pathology, Diagnosis, Symptoms, and Treatment:* By WILLIAM BILLINGTON, M.S. Lond., F.R.C.S. Eng., Senior Surgeon to Out-patients, Queen's Hospital, Birmingham. With 12 full-page plates and illustrations in the text. London, New York, Toronto, and Melbourne: Cassell and Company, Limited. 1910. Pp. 167. Price 7*s.* 6*d.* net.

THERE are few matters about which greater diversity of opinion exists than the importance of moveable kidney. Though nearly all are agreed that serious symptoms may arise in consequence of abnormal renal mobility, yet while some consider that urgent symptoms very rarely result from moveable kidney, others consider that the most diverse symptoms, often of the greatest severity, may be directly or indirectly due to this cause. Mr. Billington has for several years devoted a great deal of attention to the subject, and he is convinced that moveable kidney is an important factor in the production of many serious symptoms, and that fixation of the kidney will in many cases prove exceedingly effective. He does not operate on every case of moveable kidney which he sees. Relief has been afforded to some by belts and other forms of mechanical support, but he has found it necessary to operate in 230 cases, and he has fixed in place more than 350 loose kidneys.

With regard to the frequency of the condition, the author believes that it is less common among the general community than appears at first sight, but that among the ailing and weakly it is far more often met with. He agrees with all other observers that the affection is much more common in women than in men, and if only the operations were considered the comparative frequency would be 8 to 1; but he believes that these statistics represent the frequency in

men to be greater than it is, for the man with a loose kidney is more likely to seek operation, perhaps, than is the woman. Trauma resulting from muscular overstrain is, he considers, the most common cause of the affection, and he attributes also some of the responsibility to corsets, especially when they are high-waisted.

The operation which Mr. Billington prefers consists in raising a triangular flap of kidney capsule from the upper half of the organ, and below this silkworm sutures are passed through the capsule of the lower half of the kidney. The kidney is pushed up until the base of the flap is level with the lower border of the last rib. The flap of capsule is passed over the rib and stitched to the capsule below. The silkworm-gut sutures are made to pass through the muscle and skin above the incision, and are there tied over a roll of gauze. As to the results of the 350 operations, two deaths occurred, but in neither case was this occurrence apparently due to the operation. Mr. Billington is very satisfied with the effect of the operative treatment, both as to the fixation of the kidney and the relief of symptoms.

There is certainly something to be said in favour of nephropexy, but we are inclined to think that Mr. Billington's enthusiasm has carried him a little farther than most medical men would go. That in certain cases mobility of the kidney may reflexly produce troublesome symptoms we are willing to acknowledge, but we cannot accept the widespread influence which some would attribute to this frequent lesion. We should like to see in a future edition of this work a list of all the cases operated upon by Mr. Billington with the results obtained.

---

*A Text-book of Veterinary Anatomy.* By SEPTIMUS SISSON, S.B., V.S., Professor of Comparative Anatomy in Ohio State University, Columbus, Ohio; Member of the American Association of Anatomists. With 588 illustrations. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 826. Price 30*s.* net.

THIS is one of those excellently illustrated text books of anatomy of which so many have been issued in America, but it possesses the distinction of being one of the very few that are devoted to the anatomy of the domesticated animals. A great deal of care has been lavished on the preparation of the book, both by the author and by the publishers, and the result is a very handsome treatise on veterinary anatomy. The book is profusely illustrated, for it contains 588 figures, many of which are coloured, and several of them are original. Most of the new illustrations are done from photographs, and are in every way satisfactory; most are included in the chapters dealing with the digestive and respiratory systems; and it is in the description and illustration of the viscera that the book has made the most welcome additions to the text-book literature of veterinary anatomy. The remaining illustrations are taken from the beautiful plates of Ellenberger and Baum or from the work of Professor Schmaltz.

The method of the book consists in describing the body system by system, and dealing under each heading with the organs of the horse, the ox, the pig, and the dog; while in the case of the digestive system the viscera of the sheep are also included for the sake of comparison. The science of veterinary anatomy has arrived at a stage in which it has corrected many wrong impressions concerning the natural form of most of the viscera, a stage already passed through in the case of human anatomy; for the introduction of formalin hardening by intravascular injection has naturally modified the views of veterinary anatomists, just as it did those of the human anatomist. The author has therefore been at pains to secure illustrations done from photographs of good specimens of the normal viscera hardened *in situ*, and in this he has well succeeded; he has also called to his aid the knowledge gained from the preparation of frozen sections carried out during the last ten years at the Ohio State University. He has presented the whole in a text-book, the general make-up of which is excellent.

---

## LIBRARY TABLE.

*Hernia: Its Causes and Treatment.* By R. W. MURRAY, F.R.C.S. Eng., Surgeon, David Lewis Northern Hospital, Liverpool; late Surgeon, Liverpool Infirmary for Children. With 62 illustrations. Second edition. London: J. and A. Churchill. 1910. Pp. 184. Price 6*s.* net.—This is the second edition of a very readable treatise on hernia which Mr. Murray has written dealing especially with its etiology and its treatment. He is a supporter of Mr. R. Hamilton Russell of Melbourne in believing that the presence of a sac is the essential cause of hernia, and he maintains that the really necessary part of the operation for the radical cure of hernia is complete removal of the sac, a doctrine and mode of treatment which are made to apply not only to inguinal hernia, for which the theory of origin was first formed, but also to femoral hernia. There is very much to be said in favour of the congenital origin of a large proportion of herniæ, especially of those passing through the inguinal canal, and every year an increasing number of medical men accept this theory, but to apply it to all cases is perhaps carrying the view too far.

*Atlas und Grundriss der Verbandlehre für Studierende und Aerzte.* (*Atlas of Bandaging.*) Von Dr. ALBERT HOFFA, a.o. Professor an der Universität, Berlin; Geh. Medizinalrat, Direktor der Universitäts-Poliklinik für Orthopädische Chirurgie. Nach der Verfassers Tod bearbeitet von Privatdozent Dr. RUDOLF GRAHSEY, München. Lehmann's Medizinische Handatlanten, Band 13. Vierte, wesentlich vermehrte Auflage, mit 170 Tafeln und 134 Textabbildungen. München: J. F. Lehmann. 1910. Pp. 152. M 10.—We have on many occasions commended the volumes issued in this series, and the favourable opinion which we have expressed with regard to other books belonging to it is certainly equally fully deserved by the volume before us. It is always difficult in preparing a work on bandaging to know where to draw the line between those forms of bandaging of proved utility and those which are merely fantastic variations. We think that Dr. Rudolf Grahsey, who is responsible for this fourth edition, is to be congratulated on the result of his labours. The descriptions are brief and to the point, and the diagrams represent very accurately the various forms of bandage. In most cases the drawing of the bandage applied is accompanied by a diagrammatic key-picture which shows clearly how the bandage should be put on. The application of splints is also shown in figures, and the varieties of trusses illustrated by various figures are also described.

*Pathogeny of the Neurasthenic States.* By Dr. PAUL DUBOIS, Professor of Neuropathology at the University of Berne. Authorised translation by EDWARD G. RICHARDS. London and Edinburgh: William Green and Sons. Pp. 61. Price 2*s.* net.—This is a reprint and translation of a communication presented by Professor Dubois at the Tenth French Congress of Medicine held at Geneva in September, 1908, and in it the reader will find a lucid summary of the views on the psycho-neuroses which he has promulgated in various papers and volumes. In assigning a common origin to the "neurasthenic states"—for Professor Dubois is a convert to the view which prefers the conception of "episodic syndromes" to that of "morbid entities"—in a primitive mental defect, a "psychasthenia" in the general sense, he appears to postulate too much, for in many

patients who have one attack of nervous debility, from which a complete and lasting recovery is made, we fail to find any trace of that fundamental inferiority which Dr. Dubois describes, nor do we require its aid to explain the symptoms. But although the reader may be unwilling to subscribe to all of the author's dicta, he will appreciate the eminently practical spirit that characterises this essay and the clinical acumen of its writer.

*The Vision of the Young Man Menelaus: Modernist Studies of Pentecost and Easter.* By the Author of "Resurrectio Christi." London: Kegan Paul, Trench, Trübner, and Co. 1910. Pp. 211. Price 2s. 6d. net.—It is difficult, and might possibly be unfair, to attempt to summarise the argument in this book, which is concerned with the discrepancies in the differing versions of the resurrection of Christ. These versions present features that can only be described as mutually contradictory, as many scholars have fully recognised. In an endeavour to reconcile the discordances the author develops the hypothesis that many of the Christophanies were subliminal, and supports his opinion by an appeal to the dicta of what he chooses to call the new science of religious psychology, the chiefest assumption of which is that "if God works directly in man He must work through the subconsciousness." Taking this frank assumption for a basis, the author proceeds to elaborate solutions of the problems concerned which culminate in the statement that "subliminal telepathy is only another name for the Communion of Saints." Not only does he take the "facts" of telepathy as proved, and talk of it as a recognised commonplace, but he also appeals so complacently to the phenomena of the subconscious mind, as though that conception in an organised and unvarying form were part of the current coin of the world of thought, that it is hard to believe he can be aware of the difficulties which surround the subject. There are half a dozen differing conceptions of the subconscious mind, some at least of which are mutually incompatible, and from its very nature the mechanism of the phenomena with which we suppose the subconsciousness to be concerned must escape us whenever we attempt to analyse it. If we are once to grant, as the author would have us, "the ability of the subconsciousness to acquire telepathic impressions from outside," then we can follow his argument in its entirety, but whether our admiration of the Apostles of old is thereby augmented is another matter. We recommend our readers, however, to judge the book for themselves; they will be struck alike by the erudition of the author and the spirit of reverence with which the subject is handled.

*Dr. Grey.* By STEPHEN ANDREW. London: Greening and Co., Limited. 1911. Pp. 320. Price 6s.—Stephen Andrew, who acknowledges in his dedication that he is a medical man, has written a book which is quite worth reading. It is not a novel, for there is no plot, no particular story, and the love interest is of quite a secondary character. Incidentally, we do not like a heroine who calls her lover "Arthur boy." But as a picture of the trials and struggles of a general practitioner whose lot lies among the poor, and of the manners and customs of those poor, it is good. It cannot be placed in the same rank with "Liza of Lambeth," for Mr. Andrew does not write with the grim aloofness which Mr. Maugham, also a medical man, employed so effectively in his first literary work; "Liza of Lambeth" is permeated with the atmosphere of the Virgilian Fatum; such things as are described therein happen because they must happen. Mr. Andrew's pictures of medical life are simply and accurately drawn; St. Dorothea's Hospital, at which Dr. Grey studied, had one curious custom in which we hope it is unique among London hospitals—namely, that the house physician on his rounds at night examined all the new cases which had been admitted during the day, but otherwise he draws a faithful portrait of the modern *interne*. The pictures of club practice are lifelike, and the descriptions of the various types of practitioners with whom Dr. Grey comes in contact in his search for a practice are very well done. The practitioner who, buried in a little country practice, is on the verge of becoming a drunkard, owing to the loneliness of his position, is now an obsolete type, but such cases occurred 50 years ago, especially in the fen country, where many a man took to opium eating as a remedy in malaria, and as a stimulant and narcotic. Dr. Grey eventually settles down in a midland ironworks town, where his experiences are described with much realism. One of his friends, a Radical journalist with whom he has many a discussion on medical politics, suggests as a remedy for poverty, both that of the poor medical man and that of his poor patients, the formation of a State Medical Service, a question of great moment just now.

## JOURNALS AND MAGAZINES.

*Quarterly Journal of Microscopical Science.* Edited by Sir E. RAY LANKESTER, K.C.B., F.R.S., with the coöperation of ADAM SEDGWICK, M.A., F.R.S., SYDNEY J. HICKSON, M.A., F.R.S., E. A. MINCHIN, M.A., and GILBERT C. BOURNE, M.A., F.R.S. December, 1910. London: J. and A. Churchill. Price 10s.—This number, the first part of Vol. LVI., is mainly occupied by a contribution to the Embryology of the Marsupialia, by Professor J. P. Hill, containing an account of the principal results and conclusions at which he has arrived after a protracted and much interrupted study of an extensive collection of early developmental stages of marsupials, ranging from the fertilised egg to the blastocyst, in which the two primary germ-layers are definitely established. The material at his disposal was obtained in Australia and comprised a fairly complete series of stages of the native cat (Dasyurus viverrinus), together with a few early stages of other marsupials—namely, Parameles and Macropus. Our knowledge of the processes of cleavage and germ-layer formation in the marsupialia is based largely on the observations of Selenka on the development of the Virginian opossum. The divergence between Professor Hill's and Selenka's results is explained by the fact that Selenka's early material was derived from but two pregnant females, and consisted of many eggs which had failed to develop normally. The conclusions at which Professor Hill arrives are, first, that the embryonal or formative region of the unilaminar marsupial blastocyst is the homologue of the inner cell mass or embryonal knot of the eutherian blastocyst; and, secondly, that the extra-embryonal or non-formative region of the same is the homologue of the extra-embryonal ectoderm of the Sauropsida and Monotremata, and of the trophoblast of the Eutheria. As regards the first conclusion, there is not likely to be much difference of opinion, but Professor Hill feels that the second will prove neither obvious nor acceptable to those mammalian embryologists who, with only Selenka's account before them, have formulated other views as to the morphological nature of the outer enveloping layer of the eutherian blastocyst. Specialised though the marsupials undoubtedly are in certain features of their anatomy, Professor Hill's observations do not afford any ground for the supposition that their early ontogeny is also of an aberrant type; on the contrary, his observations tend to show that the marsupial type of early development, not only readily falls into line with that of Eutheria and Prototheria, but furnishes a key to the correct interpretation of that extraordinarily specialised developmental stage, the eutherian blastocyst, and bridges the gap in our knowledge of the way in which the transition from the monotrematous to the eutherian

type of development has been effected. The article is illustrated by plates, reproductions of drawings executed with the aid of Zeiss's camera lucida; these plates contain 85 drawings, each one of which is a perfect work of art. Included in this number is a memoir by Dr. Iwaji Ikeda on a deep-sea echiuroid animal, a very curious and hitherto undescribed species belonging apparently to the genus Hamingia. There is also a description of the blood of certain coleoptera, Dytiscus marginalis and Hydrophilus piceus, by Dr. Wakelin Barratt and Mr. George Arnold, from the Cancer Research Laboratory of the University of Liverpool. The circulating fluid of these coleoptera resembles mammalian blood in so far as it is an albuminous fluid and contains cells. The fluid part resembles mammalian blood plasma in containing proteid coagulable by heat, and a globulin held in solution by the saline constituents of the fluid. The cellular elements are represented by phagocytes and small round cells, whose characteristic feature is the scanty cytoplasm surrounding the nucleus. The circulating fluid differs in its low osmotic pressure and in the absence of cells containing hæmoglobin, no oxyphile granules are present, and no spontaneous coagulation of the blood takes place on standing. In both insects oxygenation appears to occur by direct transfer to the tissues of oxygen supplied by the tracheal vessels, the blood plasma not serving as a medium of exchange.

*L'Hygiène.*—The second year of this illustrated monthly commences with the December issue, and the high level of excellence to which we have previously drawn attention is kept up. In the latest number Dr. Maurice de Fleury writes an elegant and eloquent note to the memory of the late Professor Raymond. Professor Courmont of Lyons discusses the modern construction of hospitals, and there are the usual articles dealing with cookery and gastronomics rather from a medical standpoint. The principal contribution to this number, however, is an essay, by Professor Charles Richet of the Academy of Medicine, on physical education, humorously and effectively illustrated by Maurice Taquoy. Writing gravely, though in a sportive way, on the ancient theme of the relation of the health of the body to the health of the mind, Professor Richet lays down the following simple formula: "Sur les huit heures de repos, deux heures de travail intellectuel aux artisans; deux heures d'exercice physique aux intellectuels." The truth of this dictum he proceeds to establish on physiological grounds.

# New Inventions.

## A NEW THERMOMETER CASE.

Messrs. Down Bros., of 21, St. Thomas's-street, London, S.E., have made for me a new thermometer case to which I wish to draw the attention of the medical profession. This case is divided into two chambers, which are separated by a perforated partition. The smaller chamber screws on to the larger, and is made to contain a portion of a formalin tablet. The formaldehyde vapour

liberated from the tablet passes up through perforations into the large chamber, which contains the thermometer. The advantages of an antiseptic thermometer case are obvious, especially when there is no fluid which can leak into the pocket. It is only a quarter of an inch longer than the ordinary case, and is sold by Messrs. Down Bros. at the price of 2*s.* 6*d.*

F. W. MORTON PALMER, M.D. Cantab.

Teignmouth.

## "TABLOID" EMERGENCY CASE FOR PHYSICIANS.

IN order to provide a convenient receptacle for those special medicaments and remedial agents which a physician would wish to have by him in case of sudden emergency, Messrs. Burroughs Wellcome and Co., of Snow Hill Buildings, London, E.C., supply a special outfit consisting of a light but strongly constructed hand-bag made of steel, and covered inside with morocco and outside with cowhide. It opens with a spring catch and is divided into three separate compartments, which are kept free from dust by hinged and leather-covered steel doors, so that the contents of the case, whether frequently required or not, are always ready and in good condition when occasion arises for

their use. The weight complete is about 5 pounds. The case, which measures 8¼ by 5½ by 3¼ inches, contains "Vaporole" products (for hypodermic use) of "Ernutin," pituitary (infundibular) extract, "Hemisine," strychnine, sulphate and morphine hydrochloride, a B. W. and Co. all-glass hypodermic syringe with two needles, "Tabloid" hypodermic products, "Soloid" sodium chloride and "Soloid" corrosive sublimate, and "Wellcome" Brand chloroform in tubes, apparatus for intravenous injection, œsophagus tube, bandages and dressings.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam:* Dr. S. J. de Lange has been recognised as *privat-docent* of Microscopic Anatomy of the Nervous System.—*Berlin:* Dr. Claus, Oberarzt of the Otological Polyclinic of the Charité, has been appointed Director of the Laryngological and Otological Clinic of the Rudolph Hospital. Dr. Josef Koch has been granted the title of Professor. Dr. Kurt Adam has been recognised as *privat-docent* of Ophthalmology, Dr. P. Reyher as *privat-docent* of Children's Diseases, and Dr. Eugen Joseph as *privat-docent* of Surgery.—*Breslau:* Dr. Walter Hannes, Oberarzt of the Gynæcological Clinic, has been granted the title of Professor.—*Halle:* Dr. Hermann Gocht, whose specialty is orthopædic surgery, has been granted the title of Professor. Dr. Alfred Denker of Erlangen has been offered the chair of Otology.—*Jena:* Dr. Ludwig Wrede has been recognised as *privat-docent* of Surgery.—*Königsberg:* Dr. Hoeftmann, whose specialty is orthopædic surgery, has been granted the title of Professor.—*Leipsic:* Dr. Hans Vörner has been recognised as *privat-docent* of Dermatology.—*Munich:* The University Polyclinic which used to be in the Sonnenstrasse has been removed to the fine new building in the Pettenkoferstrasse, which was opened with an imposing ceremony.—*Münster:* Dr. Otto Krummacher has been recognised as *privat-docent* of Physiology.—*Naples:* Dr. Raffaele Janni has been recognised as *privat-docent* of Topographical Anatomy and Operations.—*Padua:* Dr. Vincenzo Mario Carletti and Dr. Pier Diego Siccardi have been recognised as *privat-docenten* of Internal Pathology, and Dr. Gino Dedin as *privat-docent* of Pædiatry.—*Palermo:* Dr. Stefano Barba, Dr. Giovanni Di Cristina, and Dr. Pietro Salvatore have been recognised as *privat-docenten* of Internal Pathology, and Dr. Giuseppe Sulli as *privat-docent* of Forensic Medicine.—*Paris:* Dr. Dejerine, professor of internal pathology, has been appointed to succeed Professor Raymond as Clinical Professor of Diseases of the Nervous System at the Salpêtrière.

THE LANCET.

LONDON: SATURDAY, JANUARY 14, 1911.

## The Report for 1909 of the Medical Officer of the London County Council.

THE eighteenth annual report of the medical officer of health for the administrative county of London has been issued during the present week. The volume has been submitted to the London County Council by the chairman of the Public Health Committee, Mr. W. FREEMAN BARRETTS, who, in a brief introductory paragraph, records his official sanction to its circulation, instead of prefacing it, after the manner of some of his predecessors, with a commentary of his own, which, truth to say, was a somewhat superfluous proceeding. In each of its departments Sir SHIRLEY MURPHY'S report manifests the same high standard of excellence as that which has characterised its several predecessors.

The subject-matter is arranged under convenient headings which have been carefully indexed to facilitate reference. The first part deals statistically with the incidence of disease and of mortality from the principal causes in the several districts of the metropolis. The second, which in recent reports has tended to become the most important part, treats in detail of the administrative proceedings of the County Council, and particularly of its action in supervising and coördinating the work of the metropolitan sanitary authorities, and shows evidence of the steady improvement in the public health and sanitary condition of the metropolitan area which has prevailed since the establishment of the County Council, and presumably because of that event. Fiscal considerations make it obvious that under no system of merely parochial government could the vast and costly schemes have been accomplished by which many of the most pestilential areas of the poorer parts of London have been swept away. If proof of this contention were needed the persistence in these areas of notoriously wretched conditions throughout the long period of vestry control would supply it in abundance. In striking contrast with these conditions may be placed the auspicious results that have been achieved by the County Council within the first vicennium of its existence. Some of these results are already manifest; they consist in the betterment of dwellings for the working classes, the widening or opening out of narrow streets, courts, and alleys, the demolition of unhealthy areas and the provision of open spaces for the recreation of the inhabitants—in a word, the progressive sanitary improvement of the metropolis generally. We sincerely trust that the London ratepayer, who undoubtedly has to bear the burden, will regard these benefits as full compensation for the heavy expenditure incurred. Many of the results of the Council's operations are not as yet fully apparent, and for their complete fruition we must look to the future, and the exceptional powers for the protection of the public health which the County Council has obtained from Parliament in the successive General Powers Bills of recent years. We do not know whether a complete list of these powers has been published, but from the detailed accounts contained in Sir SHIRLEY MURPHY'S successive reports we are convinced that many of them are of substantial and far-reaching importance. In recent years, at any rate, the supreme governing body of the metropolis has become conspicuous among English municipalities as an earnest and successful promoter of sanitary legislation; and there is no reason to doubt that as time goes on it will acquire still more perfect equipment for the discharge of its manifold responsibilities as custodian of the health of the community. Among a multitude of special powers conferred on the Council we may particularise those which are designed to secure a higher standard of cleanliness and comfort in dwellings occupied by the labouring classes. Only recently, for instance, the Council has obtained legal authority to require the provision of suitable cooking arrangements in tenement houses, for the supply of water to the upper storeys of such houses, and for the cleansing of inhabited rooms and their contents from vermin. Again, even so recently as last year, the powers of the Council were still further strengthened by the addition of clauses requiring provision of adequate arrangements for the storage of food. A further important provision contained in the General Powers Bill of the same year empowers the metropolitan sanitary authorities to secure that in all places where food is prepared for sale the conditions under which it is dealt with shall conform to reasonable sanitary requirements. In this way the many thousands of restaurants, cook-shops, and other like places where food is prepared for the working-classes will be brought under supervision, and conditions of cleanliness will be enforced as regards, not only the premises and utensils, but also the food itself and the persons employed in its preparation. Among other exceptional powers, the due enforcement of which will undoubtedly tend to improve the health and comfort of Londoners generally and for which the Council has obtained Parliamentary sanction, are those for the regulation of offensive trades, and for the compulsory cleansing of verminous persons in school and elsewhere.

To the action of the London County Council in administering these powers, as well as to other matters dealt with in Sir SHIRLEY MURPHY'S report, we shall refer in detail. Meantime we make these brief allusions in order to show that in a relatively short period since the inauguration of the London County Council it has been entrusted with extraordinary powers for the protection of its citizens from disease which it has used with great discretion. We direct particular attention to this fact, in the hope that other large municipalities may be encouraged to acquire similar powers and to employ them with a like care.

# Forthcoming International Exhibitions and Congresses.

A GLANCE at the Diary of Forthcoming Congresses which we publish from time to time in our columns will show that we are on the threshold of a year of special activity in all that relates to national and international congresses and exhibitions. This is the more satisfactory as, at least in respect to international exhibitions, we have, as a nation, managed recently much better than we were wont to do. Formerly, if the British Government decided to take part in an international exhibition, it acted as if such a thing had never happened before and was never likely to happen again. A Commission was appointed on each occasion to look after the interests of the country, but it was dissolved when the exhibition was over. All the experience acquired by that Commission was lost. There was no continuity and no tradition in the way which we dealt with international exhibitions. Other countries have for years made better use of that most valuable of all assets—experience. In Germany the Government, and in France the Government and some of the larger municipalities, have been able to carry forward from exhibition to exhibition the accumulating lessons of the different occasions by the institution of standing committees. Nothing of the sort has in any case taken place with us. British exhibitors have had no experienced Government officials to advise them and never quite knew what expense or trouble was in front of them. The would-be exhibitor was left to deal unaided with the railway rates of the various countries, the rates of water carriage, and the formalities of the Custom-houses. On the exhibition ground itself, the costs of hiring stands and the expense of their installation, their lighting, water-supply, and so on, all wore the appearance of so many snares to our exhibitors unless they had frequently been through the ordeal. The necessary outlay seemed preposterous because it was unexplained. No wonder that many British exhibitors were discouraged, and that the British section at these exhibitions was too often not worthy of the position of the nation in respect to our numerous industries. This has now been changed and the first evidence of the good results obtained was given last year at the Brussels Exhibition.[1] A permanent department has been created at the Board of Trade whose mission it is to deal with the national part to be played at these exhibitions. The exhibitor will now find that the rates for carriage of his goods by land or sea have all been arranged for him and that he will profit by considerable reductions on the usual tariffs. At the international exhibition itself, where the Government is recognising the affair, British authorities take charge of his consignments, provide men to unpack them, and help him to "dress" his show and decorate it in harmony with the entire section.

Whatever lessons may have been learnt in Brussels, where this activity of the Board of Trade was first manifested, will be applied at the next exhibitions. It happens that the particular experience of Brussels was of a most dangerous character. No one will have forgotten the terrible fire which destroyed the entire British section. The result is that never in the world's history have such elaborate precautions been taken against fire as those now in course of preparation at the Turin exhibition, and more especially in the British section. First, at Turin itself 20 fire stations are admirably organised, the water-supply is ample, and the pressure sufficient. At the exhibition all the woodwork must be covered over with non-inflammable asbestos paint. Drapery also must be dipped in chemicals and rendered uninflammable. Hydrants will be placed at 38 yards distance from each other, with a specially trained watchman knowing how to use them. The walls, the flooring, and all parts of the building will be constructed with a view, not merely to the prevention of fire, but so that they may be easily reached by the fire brigade, while any amount of emergency exits are to be provided. Similar precautions will be applied at the Arts International Exhibition of Rome, so that the utmost care and forethought have been displayed in the endeavour to prevent fire and such accidents as menace life and property. Exhibitors and visitors may rest assured that never before in the history of exhibitions have such carefully-thought-out proceedings been taken. These measures will serve as object lessons for the International Exhibition of Industry and Labour which is also to be held at Turin this year. The prevention of accidents and of trade diseases, and the compensation and medical treatment of the victims, constitute, we need hardly remark, an important phase of the medico-economical problems of the day. These questions will surely form a very practical side to the great International Sanitary Exhibition to be held at Dresden from May to October. Here there should be much to learn, for Germany excels in the hygiene of the factory and workshop, while in England progress is more marked in domestic hygiene. This seems indicated by the fact that the reduction effected during recent years in the prevalence of pulmonary tuberculosis is more evident among women in England and among men in Germany, for, generally speaking, despite modern increase in female labour, women stop at home and men go out to work. Doubtless we shall hear more about this question at the International Congress on Tuberculosis which meets at Rome from Sept. 24th to 30th. This is a very important Congress, and it assembles every three years. The last was held in 1908 at Washington, U.S.A., when some 6000 members were enrolled and some fairly good scientific work was done. The time that has elapsed has been fruitful, and we may confidently expect a valuable meeting of the leaders of thought.

Other international congresses convoked for this year, which will be of interest to medical men, comprise the Congress for the Blind which will meet at the end of February in Cairo. In May we have the Congress on Opium at the Hague; in June, the First Congress of the International Medical Association for the Prevention of War, at Paris, and certainly no one can have greater knowledge of the evils of war than the medical men who tend the wounded. There are also a number of international congresses on special branches of medical science, such as one on pathology, at Turin; on infant mortality, at Berlin; on alcoholism, at the Hague; on marine hygiene, at Genoa; and on dermatology, at Rome.

[1] See THE LANCET, August 20th, 1910, p. 589.

All these last-mentioned congresses, together with the very important Congress on Tuberculosis, meet in September. Certainly this is the most favourable month for such gatherings, but this great clash of congresses is unfortunate. Most specialists will feel obliged to attend their own particular meeting, and will be unable to be present at congresses less intimately connected with their work, whereby these congresses will lose that criticism from the outside which is of the greatest practical value, and which destroys any tendency to abuses of mutual admiration. There is still great need of better international organisation in these matters. This was forcibly stated when the International Association of the Medical Press met at Budapest the year before last. It was then even urged that perhaps the International Committee of the Medical Press might serve as the link of union between all the international congresses of the medical and allied sciences. No further movement has been taken in this direction, but no one can deny that more systematic arrangement is needed, and perhaps it might be obtained in this way.

## British Spas from the International Point of View.

A STRONG contrast is noticeable between the large number of visitors, wholly or partly in search of health, from Great Britain to foreign spas and the very few foreigners who from like motives seek health or amusement, or both, in the spas and watering-places of this country. The reasons for this disparity are discussed and critically examined with clear insight by Dr. NEVILLE WOOD in an article on British Health Resorts for Foreign Invalids, which appeared in THE LANCET of Jan. 7th, p. 12. Dr. WOOD at once takes the broad ground that it is short-sighted policy, however patriotic it may seem, to exhaust our efforts in endeavours to keep the Briton from foreign countries, instead of demonstrating that British health resorts offer substantial benefits to foreign invalids also, and aiming thus to redress the adverse balance. A permanent commercial success in the long run is dependent rather on supplying the thing really needed than in endeavouring to palm off on him "something just as good." There are patients to whom Great Britain cannot supply the things needful, or at least desirable, for their greatest advantage. Such patients ought to go abroad, if they can afford it, where these desirables can be found, since the rapidity or completeness of their relation to health can be aided thereby. This is particularly the case in regard to certain requirements whose effect is of the psychic order. On the other hand, there are many others who can obtain all that is requisite for them in various resorts at home. But still further—and this forms the main thesis of Dr. WOOD'S article—there are many foreigners who would find at our English health-resorts, for precisely the same reason that should lead certain Britons abroad, advantages that they could not obtain at continental spas.

Attention is often centred too exclusively on the composition of the waters at foreign watering-places, yet the composition of the waters at various British resorts is closely similar to that of one or other of the well-known spas abroad. We have in England, Scotland, and Wales types of all the principal waters—muriated, sulphuretted, indifferent, earthy, alkaline sulphated, iron, strong salt, and brine. It cannot, therefore, be solely a matter of the waters that takes so many of our British patients abroad yet brings so few foreigners to our shores. There must be some other reason or reasons for the paucity of foreign health-seekers visiting us. The explanation is partly to be found, no doubt, in lack of knowledge on the part of those living on the continent concerning the nature and existence of the medicinal waters of Great Britain. To illustrate this point Dr. WOOD mentions that in a well-known German manual describing the health resorts of Europe there is no mention of any at all in England; and, again, that in a similar French publication, in its forty-ninth year of issue, whereas six pages are allotted to Spain, two are considered appropriate for this country, while various errors and omissions sufficiently indicate the absence of competent revision. This, however, is not entirely due to indifference on the part of foreigners, for Dr. WOOD found that the editor of one such work had vainly endeavoured to procure in London any authentic account of the British spas, while a request was made to Dr. WOOD for an addendum on British seaside resorts to the German translation of his work on "Spa Treatment," as well as an offer of a French translation of a work on British spas. There is considerable difference of opinion as to the precise manner in which "spa" treatment produces its beneficial effects. Some authorities maintain that the waters themselves have but little, if any, effect, and insist that the régime to which the patient is submitted is responsible for the improvement that ensues. Other physicians, again, maintain that the waters have a very definite action, although the exact explanation of the manner in which they act is by no means definite. To these factors must be added a third factor—namely, the psychic—and this in a large number of cases is a powerful one. In the continental resorts, especially those of Germany, the daily life of each patient is carefully laid down; every detail in the hotels and environment of the town is made subservient to therapeutic measures; there are certain outdoor amusements, such as tennis, and at a few of the spas golf, to be obtained, and at many social attractions are a powerful factor. The majority of the visitors, however, are there for treatment and not for amusement, and so the whole of a patient's attention is directed to the daily routine prescribed by the doctor. From a purely medical point of view this plan has advantages. Social amusements, such as dances and concerts, are indeed provided, but for the most part they are held outside the hotels, and terminate at a seasonable hour, so that invalids may find health without being disturbed by younger visitors, who seek only pleasure and no treatment. Another feature of most of the continental resorts is the complete manner in which the surrounding country is supplied with good restaurants or cafés, whereby daily afternoon exercise is encouraged. Added to these characteristics from the point of view of the British visitor is the change from one country to another, the complete difference in thought and surroundings adding to the psychic influence which we have already mentioned. It is here that Dr. WOOD makes a

strong point, for obviously foreign invalids at British resorts would experience the advantages to be derived from a complete change of scene, environment, and ideas that our invalids experience in European sojourn.

Dr. WOOD points out one advantage which the spas in this country enjoy over some of the more favoured continental spas—namely, the cooler climate of Britain, favouring, as it does, all kinds of outdoor exercise. He describes clearly the categories of foreign invalids for whom our spas are typically suitable, including those who thrive in a relatively cool climate and are able to walk well; those who in association with a complete change of environment derive benefit from baths that are neither very hot nor taken necessarily in close succession; and, of course, those whose maladies are held to be suitable for treatment by the principal waters in this country. Foreign physicians might learn much from a visit to the spas of this country. They would find the appliances excellent in every way, and would probably arrive at the conclusion insisted on by Dr. WOOD that continental health resorts should not be regarded as competing with British health resorts nor British with continental. In this connexion a suggestive remark is made by Dr. WOOD, who has found that when treating foreigners in London the sick-room temperature usually has to be kept from one to three degrees Centigrade higher than would be tolerable to English patients. Whether this be due to the longer and colder winters of continental stations having led to more efficient methods of domestic heating, or to the more uniform exposure of the body to a higher mean temperature during the warmer summers, it certainly suggests that foreign invalids may with advantage to themselves find in many of our winter stations convenient summer resorts at the time when they are largely deserted by Britons. British and continental health resorts might prove complementary to one another in this respect, as, probably, in many others.

"Ne quid nimis."

## THE PSYCHOLOGY OF INTIMIDATION.

"No incident has of late years so impressed the Italian imagination," writes our Florence correspondent, "as the siege of the foreign anarchists in the City of London. The previous acts in the drama which culminated in Sidney-street were not without precedent abroad; the assassination of agents of the public force in the discharge of their duty is by no means unexampled, particularly south of the Alps. But the siege of the 'Fort Chabrol' in Paris, and that of the Via Ottaviano in Rome, sink into insignificance beside the blockade and bombardment of the tenement in the Whitechapel quarter, defended as it was with a desperation that taxed the resources of the 'centre of civilisation' to overcome. At first the foreign critic of the besieging party was inclined to censure, if not to ridicule, its members and equipment, but gradually, as the circumstances became known, the censure and ridicule gave place to genuine admiration of the combined forethought, promptitude, and effect with which the operations were carried out. Nothing short of the means employed could have availed the public force in the time at their disposal, and the result is being laid to heart at more than one Ministry of the Interior where the lesson it conveys may one day have to be repeated. Whether the scene of repression and capture be the interior of a garrison, or a lunatic asylum, or, as in the recent case, a criminally occupied tenement, the agencies employed must always be far in excess of those apparently sufficient. The impression on the individual or individuals aimed at must be produced that the means of capture and coercion make resistance hopeless. In lunatic asylums, especially south of the Alps, this, the psychological, element in dealing with the violently aggressive or recalcitrant subject has long been left out of account, with consequences all too deplorable both to the party coercing and the party coerced. No maniac is ever so furious as not to be impressed by the overwhelming forces antagonising him; the 'belva umana' shares the instinct of his animal counterpart in resigning himself to *force majeure*. Forty years ago the columns of THE LANCET were the arena of animated discussion on alleged deeds of violence perpetrated in lunatic asylums on patients whose recalcitrancy had goaded the *personnel* out of self-control, and cases were referred to in which the keeper had thrown the lunatic down and by travelling over his prostrate body on his knees had fractured one or more of the ribs and thus reduced the wretched man to impotency—with traumatic pleurisy as the result. Evidence was adduced that once deeds of violence, occurring rarely, if at all, in the British Isles, were by no means uncommon in France and Italy, where the *personnel* in charge of the inmates of asylums was so inadequate in number that loss of temper on the part of the keeper, goaded past endurance by refractory cases, drove him to the hideous practice of rib-breaking referred to. Such abuses having become known, the remedy of reinforcing the *personnel* and bringing it up to something like the proportion regarded as *de rigueur* in the British Isles was put in practice on the continent. The violent lunatic, overawed by the superior force antagonising him, ceased to be refractory, relapsed into sudden calm, and so spared the *personnel* the extra call on its patience, and himself the rough usage of an angry and provoked attendant. The 'psychology of intimidation,' thus recognised in treatment, now explains the lessened frequency of deeds of violence in the asylums of Southern Europe. The same influence must be used where degenerate man, exemplified in the violent criminal, the revolutionary desperado, the law-defying, law-subverting anarchist, manifests his baneful activities; he too must see the hopelessness of contending with overwhelming force."

## CHOLERA IN MADEIRA.

WHILE the cholera epidemic at Madeira appears to be undoubtedly on the decline, the island is still practically isolated and postal communication is fitful. We have received a further letter from our special correspondent there, dated Dec. 31st, 1910, in which he says: "The official figures on the 30th of December show a total of 1245 cases and 360 deaths since the commencement of the epidemic. In Funchal itself 1 case was reported on the 30th inst., and the outlying parishes yielded 5 cases. The activity of the disease seems far spent, and the mortality, much lessened now, was never very heavy in percentage. No English person has been attacked, nor any of the Portuguese above the lowest stratum of their society. The medical work has been good, and illustrates emphatically the proficiency of our Portuguese colleagues in modern bacteriological and clinical methods." It is interesting to receive so excellent a report of the progressiveness of our Portuguese colleagues, and we hope that their efforts will now be vigorously seconded and their

requirements promptly met by the Portuguese Government, so that the island may not suffer too severely from the protracted lack of communications. One of the chief obstacles in all such epidemics is the hostility, through ignorance, of the lower classes, whereby efforts to improve the sanitary conditions and prevent the spread of disease are either secretly frustrated or lead to active rebellion. According to the *Times* correspondent, the latter condition has occurred in Madeira, the populace resisting the removal of cases for isolation, so that local troops had to be called out, and it has even been found necessary to supplement them by sending from Lisbon a battalion of the Sixth Infantry 600 strong.

## THE IPECACUANHA TREATMENT OF AMŒBIC DYSENTERY AND ACUTE HEPATITIS.

SOME drugs, like some fashions in dress, have their day and are soon forgotten. Occasionally, however, a particular remedy is revived and comes again into favour. A recent instance of this is the employment of ipecacuanha in the treatment of amœbic dysentery and its formidable sequela acute hepatitis. For a long time this drug enjoyed a high reputation, being regarded almost as a specific by some authorities like MacLean. Gradually, however, the drug lost its reputation and sank into disuse, except, perhaps, with some practitioners in India who had proved its utility by long experience. The reasons for this waning of popularity of ipecacuanha with the profession are not easy to find. Perhaps some gave it up because there was no scientific explanation of its apparently specific action. Others may have had lack of success through administering it in insufficient doses or without observing the due precautions which are necessary. Some may have abandoned it finding that the drug lost its special properties when kept for any length of time in a hot climate, or it may have been employed in some of the bacillary forms of dysentery, in which its action appears not to be so potent. It is largely through the efforts of Major Leonard Rogers, professor of pathology in the Medical College, Calcutta, that ipecacuanha has recently been restored to favour. In his well-known work on fevers in the tropics he pointed out that the ipecacuanha treatment of amœbic hepatitis prevented the occurrence of suppurative hepatitis, or tropical liver abscess; that this complication could be entirely avoided if the treatment by ipecacuanha were employed. This, he suggested, might well be included in the list of maladies which recent research work has largely conquered. Deaths from hepatic abscess in the British army in India have, it appears, within the last three years been reduced by nearly two-thirds, and they are still decreasing. Further valuable evidence in support of Major Rogers's contentions has been recently forthcoming in the form of a series of papers read before the Medical Section of the Asiatic Society of Bengal by Colonel H. W. Pilgrim, I.M.S., surgeon-superintendent, Presidency General Hospital, Calcutta: Lieutenant-Colonel F. J. Drury, I.M.S., principal, Medical College, Calcutta; Lieutenant-Colonel J. T. Calvert, I.M.S., professor of materia medica, Medical College, Calcutta; Lieutenant-Colonel A. H. Nott, I.M.S., civil surgeon, Howrah; and Captain Greig, I.M.S. These papers were published in September last in the pages of our contemporary, the *Indian Medical Gazette*, and have now been issued in pamphlet form, containing also a brief summary of the discussion which followed the reading of the papers. The evidence of Colonel Pilgrim is specially convincing. He asserts that during the last three years all his cases of dysentery treated by ipecacuanha have done well, as also his cases of hepatitis. In not a single case of dysentery so treated has hepatitis occurred as a complication, and every patient coming under his care with hepatitis already established has, under ipecacuanha treatment, recovered without passing through any stage of suppuration. In these days when faith in drugs has grown weak the evidence brought forward by Major Rogers and supported by Colonel Pilgrim and his colleagues deserves the most serious attention of all who are called upon to treat amœbic dysentery and its sequelæ.

## THE PROPOSED ESSEX MEMORIAL TO THE LATE KING.

THE Earl of Warwick, Lord Lieutenant of Essex, recently presided at a public meeting held in the county town to agree upon some form of memorial to the late King, it having been decided at a previous meeting that the memorial should be one having for its object the prevention and cure of consumption on "the Lyster system." Immediately the meeting commenced it was obvious that the conveners had no definite proposals to submit, relying upon the resolution passed at the previous meeting that an association should be formed with the object of encouraging local authorities to provide shelters, such as are known as "Dr. Lyster's shelters," for the isolation of consumptive patients during treatment. Dr. Thresh, the county medical officer of health, pointed out that if the proposed association limited its functions to merely encouraging authorities to provide shelters the movement could hardly be considered a memorial to the late King. He suggested that funds should be raised for providing a central institution for the reception of cases of phthisis, and that it should be organised on such a basis that the board of management would not be dependent upon private subscribers for its support. The suggestion did not meet with general approval, but no other feasible proposition was submitted. Certain of those present wished to have the Lyster system, and the Lyster system only, and appeared to be under the impression that it could be adopted without the provision of any institution. What the Lyster system is was not defined. Mr. A. E. Lyster, medical superintendent of the Alfred Boyd Memorial Sanatorium, and Poor-law medical officer for the Great Baddow portion of the Chelmsford Union, has popularised the use of canvas tents or shelters for the treatment of phthisis cases under his care, these shelters being erected in backyards or gardens. The construction of the shelters and the methods of treatment adopted should surely have been before the meeting, as well as any statistical evidence that has been adduced to show that treatment in these shelters produces better results than can be otherwise obtained. The county of Essex can hardly adopt as a memorial to the late King the maintenance of a therapeutic system which has never been accurately defined, but which appears to mean the provision of shelters in all parts of the county, combined with supervision by a medical man, who is to devote his whole time to visiting the shelters and seeing that they are correctly used and that the patients are properly treated. The proposal can never meet with general acceptance. Sanitary authorities and boards of guardians, having the necessary legal powers, may provide shelters, but it would be unreasonable to suppose that their medical officers would welcome the interference of anything like the association proposed. The very suggestion has caused members of the medical profession to hold aloof from the memorial movement. The committee appointed to consider the memorial includes a number of representative members of our profession, and it is to be hoped that they will serve and assist in devising some form of permanent memorial which shall be worthy of the county. If the prevention of tuberculosis and its cure are

to be the objects, some central institution must be provided, and its managers must not be bound to any particular system of treatment, but must be free to adopt any system which their medical advisers believe to be the best. The suggestion made by the county medical officer appears a feasible one, and if properly carried out would provide a memorial worthy of the name. Dr. Thresh pointed out that upon a sufficient area of land a good administrative block could be erected, capable of further extension if and when desired, and shelters could be provided as required. Temporar canvas shelters may, or may not, be the best for institutional purposes, but it would be easy to compare them with the permanent accommodation provided at the Benenden Sanatorium, where the cost per bed has not exceeded £100, exclusive of land. Canvas shelters may be economical and particularly useful for home treatment, but it does not follow that they are equally economical for institutions, since the cost of maintenance and administration must be considerably greater with such comparatively flimsy structures than with shelters or ward blocks of a more substantial character.

## INFANTILE KALA-AZAR IN TUNIS.

FOR some time past the workers at the Pasteur Institute of Tunis have been engaged in studying a peculiar and special infection occurring in the children of that district. Already 20 cases are on record, and an interesting *résumé* of the chief facts at present discovered in regard to it is given by M. Charles Nicolle, the director of the Pasteur Institute of Tunis, in a communication [1] made to the Congress of Medicine at Trapani. As a rule, the disease commences during the course of the second year; occasionally it attacks children of 3, 4, or even 6 years, but this is rare. So far it has only been observed in children. All races, both European and native, living in Tunis, appear liable to its incidence, but it is more common among Italians. Its onset is insidious, and at this stage diagnosis is difficult, but when the disease is well established it presents somewhat characteristic symptoms. There is extreme anæmia, emaciation, marked enlargement of the spleen, and to a less degree of the liver, fugitive œdema, a very irregular temperature, definite acceleration of the pulse-rate, digestive disturbance, and mononuclear leucocytosis. Hæmorrhages are not infrequent and a bullous eruption may occur. In order to establish the diagnosis and to distinguish the disease from other conditions leading to enlargement of the spleen, which are not uncommon in children in Tunis, it is necessary to demonstrate the presence of the parasite. This is readily done by examining the fluid obtained by puncture of the liver or the spleen. The parasite is a protozoon of the genus Leishmania, identical in its morphological characters with that found in kala-azar in India, and also with that of Delhi boil, except that it is slightly smaller. Post mortem the only changes found are the enlargement of the liver and spleen and the red colour of the bone marrow. The parasites occur in enormous numbers in the spleen, liver, and bone marrow, less commonly in other organs. They are sometimes free, at others enclosed in the large mononuclear leucocytes. The general characters of the disease appear to be identical with those of the Indian kala-azar, but since it apparently occurs only in children, M. Nicolle and his co-workers have applied the name of Leishmania infantum to the parasite to distinguish it from the Leishmania donovani of Indian kala-azar and Leishmania tropica of Delhi boil. The protozoon of infantile kala-azar can be readily cultivated upon the medium of Novy-MacNeal, and the cultures can be repeated indefinitely. The disease can be inoculated into the dog or monkey, but in other animals only a temporary infection results, or they may be completely refractory. In the dog the infection may last for several months and then undergo spontaneous cure, or it may lead to cachexia and death. In the monkey the course of the affection is more closely similar to that in the human subject. Since it appears that the disease may occur spontaneously in dogs, M. Nicolle suggests that these animals may be the cause of the human cases. The disease appears not to be confined to Tunis, since cases have been observed in Italy, Malta, and Portugal (Lisbon). In discussing the possibility of the identity of the infantile disease of Tunis with the Indian kala-azar, M. Nicolle is of opinion that further observations upon the latter disease are necessary. Notably he recommends that attempts shall be made to grow the Leishmania donovani upon the Novy-MacNeal medium, and attempts made to inoculate dogs from these cultures. The disease has so far proved to be of uniformly bad prognosis, and no treatment, in spite of numerous trials, has proved of any value.

## THE WEATHER OF DECEMBER.

THE weather of December was very similar to that of November in its rainfall over the United Kingdom, or at all events the greater portion of it, but very different in its temperature. While November will rank as one of the coldest eleventh months on record, last month will take its place among the very mildest of Decembers. During the first three weeks the warmth ranged from between 4° and 7° above the average in all parts of the country, and the last week, although much less warm, was still mild for the time of year over a large part of the kingdom. Frost was rare even on the ground, and some localities in the south-west and west were entirely exempt. Even in London the screened thermometer only recorded frost on three nights—the 28th, 29th, and 31st—and then it was very slight. The mean temperature of the nights in the metropolis was about 6° above the average. The temperature of the afternoon was scarcely so abnormal, but the mean was as much as 4½° above that of an average December. The temperature of December may be lower than that of November, and at the same time in excess of its average, but in the present instance December was not only relatively but actually milder than November. In London the mean maximum temperature (49°) was 3° higher than the corresponding figure in November, and the mean minimum (41°) as much as 8° higher. Shade readings of 50° or a little above occurred on more than half the days over a large part of these islands; in London there were 18 days with that unusual winter mildness, and many more with readings between 46° and 49°. On the south-west coast the temperature was, of course, higher than in London; at Torquay the mean maximum was 50½° and the mean minimum only 8° lower. As might be expected from the high thermometer the wind was almost always in the equatorial quarter, the only occasions when the contrary was the case being the north-westerly to northerly current which sprang up in the rear of some of the numerous depressions as they travelled away to the continent. And as it is almost impossible to experience a mild December without the presence of a series of depressions over these islands or in their immediate neighbourhood to the northward it is not at all surprising that the month was very wet. The serious inundations arising from the heavy and almost daily rains, following a month nearly as wet, were responsible for much damage to property, but the flooded area was not nearly so extensive as it has been on more than one occasion during the past 20 years, especially in the valley of the Thames, where particular precautions were successfully

taken. All parts of England, with the exception of a few isolated localities, experienced rain much more frequently than usual, and the aggregate fall was greatly in excess of the normal. The last week, however, was comparatively dry, as well as more sunny, than the three preceding. In London (Westminster) there were 23 days on which more or less rain was registered, and the total fall—3·08 inches—was 56 per cent. more than the average for the month. In several parts of Scotland and Ireland there was less rain than during an average December; at Leith and on the north-west coast of Ireland the fall was only about 48 per cent. of the normal. The rainfall of the whole year was not excessive over the kingdom generally, although the number of days with rain was very high. In London (St. James's Park) the total was 23·37 inches, or only 96 per cent. of the average. On the south coast of Kent, on the other hand, the aggregate was very heavy, amounting at Dungeness to 35·51 inches, or 56 per cent. more than the average. In the metropolis there were 201 days with at least 0·01 inch of rain, and this number is 36 in excess of the normal. December on the Riviera was not marked by any special feature, except that rain was more frequent than usual. During the first fortnight or so the temperature in the shade during the afternoons was about 52°. Subsequently the conditions were both colder and drier. Italy was warmer than the Riviera until near the end of the month, and experienced several spells of rain.

## THE HISTOLOGICAL EVIDENCE THAT TOXINS REACH THE SPINAL CORD VIA THE SPINAL ROOTS.

AN interesting and important communication from Dr. David Orr of the County Asylum, Prestwich, and Dr. R. G. Rows of the County Asylum, Lancaster, is published in the *Review of Neurology and Psychiatry* for December last, containing an account of further experimental work on the question of toxic invasion of the central nervous system. In 1907 these observers demonstrated in a most conclusive manner that the ascending lymph stream in nerves is a path along which infection of the brain or cord can readily occur, thus establishing the reality of what is known as ascending neuritis. Our comparative ignorance, however, of the whole lymphatic system of the brain and cord, and, for that matter, of nerve roots and trunks, has led to some under-estimation of its significance for the development of certain nervous diseases, and we feel sure therefore that a consideration of the facts presented in this paper cannot fail to convince the reader tha the problems connected with the pathogenesis of many nervous conditions are on a fair way towards being solved. Poliomyelitis acuta is an acute inflammatory process; general paralysis of the insane is of a chronic inflammatory nature; but in each instance the pathological changes in the vessels and supporting tissues are not comparable with the lesions resulting from a general blood infection. Study of the cerebro-spinal fluid and of the lymph currents in the central nervous system is more likely to be of profit than an examination of the constituents of the blood. In the present series of experiments the authors placed a sealed celloidin capsule containing a broth culture of an organism under the gluteus muscle of rabbits and dogs in contact with the sciatic nerve. Three separate organisms were employed—viz., staphylococcus aureus, a diphtheroid bacillus from a case of general paralysis, and the bacillus botulinus. The histological changes induced by the toxins in the nerve were similar in each instance—a most important observation, confirming the non-specificity of the histological characters of toxi-infections. A very definite reaction was found in the whole course of the sciatic nerve, through the posterior root ganglia, and along both anterior and posterior spinal roots. The toxins induce inflammatory phenomena in the fixed tissues, such as the epineurium and the perineurium, and in the veins and capillaries both inside and outside the nerve; it is instructive to note that no reaction was observed in connexion with the arterioles. Away from the immediate neighbourhood of the toxic focus the severity of the reaction diminishes, and the character of the cell reaction changes. Thus, where the phenomena are acutest there are many proliferating fibroblasts; the further we go from this area the more plasma cells do we find, so that plasma cell formation becomes the most prominent indication of irritation in those regions where there is reason to presume that the toxin has been to a great extent neutralised by the reaction of the tissues. The hæmatogenous elements do not participate in the inflammation. The striking similarity between the perivascular changes produced experimentally by the authors and those that are so familiar in connexion with general paralysis suggests that the toxin of the latter condition is to be found in the lymphatic system. Due weight must therefore be attached to the concluding statement of the paper: "There is a great deal of evidence to show that the 'bacillus paralyticans' of Robertson and McCrae is a pathogenetic factor of much importance, but as we have obtained exactly the same morbid phenomena with two other organisms, we cannot accept the specificity attached to it."

## DISINFECTING IN RURAL DISTRICTS OF FRANCE.

FOR many years now in the large towns of France disinfecting stations have been established that are models of skilful organisation and good management. The practice of disinfection in sparsely populated villages and rural districts is, however, in quite a different position. The more scattered the population the heavier the cost of disinfection and the smaller the local revenues to meet this expenditure. The great French Public Health Act of Feb. 15th, 1902, was such a radical measure that evidently time had to be allowed for its application, but the results are now beginning to make themselves felt. Among these there has been in several departments a determined effort to grapple with the difficulties of disinfection in rural districts. We have before us a very complete and detailed account of this service as established in the department of the Seine-Inférieure, by Dr. Charles Ott, head of the sanitary service, and M. Martial Basilaire, Chief of Division of the Prefecture of the Seine-Inférieure. The principal towns of this department are Rouen, Havre, and Dieppe, and these having their own *Bureau d'Hygiène* are, of course, not under consideration. The rural service extends over the remaining 757 communes, comprising a few minor towns and nearly 600,000 inhabitants. There are two sorts of disinfection—the "shallow" or surface, and the "deep" or thorough, if we may translate literally the French words. But though these terms have been consecrated by extensive use, the authors of the report mentioned prefer to speak of disinfection during illness and disinfection after illness. The one and the other must, according to the rules laid down, be supplied at the latest within six hours of the receipt of the orders to proceed. Therefore the posts of disinfectors must be so scattered that the most distant and inaccessible dwelling can be reached from one of them within six hours. For this purpose the "surface" disinfector travels on a bicycle, as he need only carry some disinfectants with him. With these he makes a solution when he arrives, and shows those who attend on the patient how to soak the soiled linen in it, and generally how to keep the place clean so as

to minimise the danger of spreading the disease. Afterwards a sanitary motor-car brings a disinfecting apparatus that can be pulled to pieces, packed in a small space, and set up when the house is reached. In this case, objects to be disinfected are exposed for two hours to the action of formaldehyde vapour. Then there are two spraying apparatus for the walls and floors within the house; a small stove for disinfecting clothes, overalls for the disinfectors to wear, and airtight sacks in which bedding and other objects can be placed and carried away. The disinfectors are paid regular salaries and no casual labour is employed for this work. Minor disinfecting posts have been established in the chief towns of the 13 *arrondissements* that group together the 757 rural communes of the department of the Seine-Inférieure. These serve for the disinfectors who render the first aid and travel on bicycles. The sanitary motor cars are best kept in a large town, and Rouen is the most central town. In this matter we are glad to note that the position of the medical adviser has not been overlooked. By law he is compelled to notify all cases of infectious diseases, but that is all. The local authorities felt, however, that, especially by reason of the considerable moral influence he can, as a rule, exercise over his patients, the medical man might very effectively aid in the work of disinfection. First, he might prepare the patient and his attendants for the arrival of the disinfectors, then advise them to carry out strictly the instructions given, disarm all spirit of resistance, and ensure the successful accomplishment of the disinfector's task. Consequently the authorities have resolved to pay a fee of 2 francs for every notification given, accompanied by the offer to help in the sense indicated above. It is a great point that the principle of payment for such service should now be recognised in France; and altogether the organisation of disinfection in these rural districts seems to be very carefully and fully planned.

## PHARMACEUTICAL EDUCATION.

IN pursuance of the powers vested in it by Section IV. of the Poisons and Pharmacy Act, 1908, the council of the Pharmaceutical Society contemplates the framing of by-laws requiring candidates for the qualifying examination in pharmacy to undergo a definite course of tuition. It is also proposed to divide the examination into two parts, and at a meeting on Jan. 4th the council had before it a scheme, covering both objects, which had been drafted by the Examination and Education Committee. This suggested scheme, which is to be submitted to local pharmaceutical associations and schools and colleges of pharmacy with the object of eliciting expressions of opinion concerning it, embodies proposals which, if put into effect, would alter very considerably the Pharmaceutical Society's requirements as to education and examination. It proposes a division of the qualifying examination into two parts—final and intermediate. A candidate for the intermediate examination would be required to produce evidence that subsequent to passing the preliminary examination and being registered as a student he had attended lectures with regularity and had performed the accompanying work in the class and in the laboratory, in a teaching institution approved by the council. The lectures and work specified are as follows: not less than 50 lectures in botany, 25 hours' work in practical botany, 100 lectures in chemistry, 300 hours' work in practical chemistry, and 25 lectures in physics. Before entering for the final examination he would be required to produce evidence that he had been engaged for three years after registration as a student, under the supervision of a registered chemist, in the ordinary work of pharmacy, and that he had attended not less than 60 lectures and demonstrations in materia medica, 30 lectures in pharmacy, and 20 lectures in dispensing and prescription Latin, and had done 200 hours' work in practical pharmacy and 100 hours' work in practical dispensing. It is not proposed to extend the scope of the syllabus or to raise the standard of the examination. At the same meeting of the council a report from the Parliamentary and General Purposes Committee was received and adopted to the effect that the Privy Council be urged to authorise an investigation into the conditions under which the storage, compounding, and dispensing of medicines and their distribution are carried on in surgeries and dispensaries of medical practitioners and in similar establishments in Great Britain.

## THE DIAGNOSIS AND NOTIFICATION OF YELLOW FEVER.

Sir Rubert W. Boyce has stated[1] that it seemed strange that there should be obstacles in the way of the diagnosis and notification of yellow fever, and added that in all the outbreaks that he had had to investigate he had encountered them. It is not surprising that this has aroused considerable attention, and at the last meeting of the Society of Tropical Medicine and Hygiene on Dec. 16th last a medical man from Trinidad commented on what was called the "to some extent justifiable desire of the authorities to prevent notification of yellow fever cases," and deplored the fact that "the name of Trinidad undoubtedly and deservedly stinks in the nostrils of its neighbours on account of its suppression of damaging information." Another opinion communicated to the meeting by a medical man from the Gold Coast was that Sir Rubert Boyce had made a very grave assertion in declaring that there had been a universal conspiracy to deny the presence of yellow fever. "What possible reason," asked this gentleman from the Gold Coast, "could medical officers have for cloaking the disease?" The executive authority, he continued, must be slow to place a colony under quarantine, but he could not imagine that it had ever refused to do so once satisfied by the medical department of the existence of yellow fever. Perhaps the most reasonable view of the matter was put forward by Dr. C. F. Harford, physician to the Church Missionary Society and principal of Livingstone College, who observed that the facts of the case might be explained without attributing to the medical profession either an attempt to conceal unpalatable truths or ignorance in diagnosis; and until this was definitely proved it was only just to give them the benefit of the doubt, especially when it was remembered that there was no absolute scientific test of the diagnosis of yellow fever; in fact, there was every excuse for failure to recognise the disease where it was not believed to be endemic unless several characteristic cases were met with at the same time. Most writers on yellow fever emphasise the difficulties connected with its diagnosis, the symptoms being subject to considerable variations. Some cases, for example, may be of the fulminating sort and terminate fatally within 36 hours; while in other instances the manifestations of the malady may be so mild that the patients are able to go about all the time and carry on their usual avocations. Some, indeed, of the mild abortive cases present no definite clinical characters which can distinguish them from an ordinary febricula. Unfortunately, for the present, bacteriology is unable to lend assistance in establishing the diagnosis of yellow fever. It is therefore small wonder that medical men at times fail to recognise the disease, more especially at the beginning of an outbreak. When the well-marked symptoms, described in the text-books, develop the diagnosis becomes less difficult, and the disease cannot then be overlooked. Sir Rubert Boyce's views on the endemicity of yellow fever in West Africa are both valuable and interesting;

[1] See THE LANCET, Nov. 26th, 1910, p. 1552.

and his conclusions, though somewhat sweeping, may be perfectly correct. But it cannot be said that he has submitted proofs of a sufficiently convincing kind to lead to the immediate and general acceptance of his opinions. Further investigation, with the collection of additional evidence, is needed before it can be unhesitatingly asserted that yellow fever is now, and has for a long period been, endemic in West Africa. The debate on the subject will be continued at the meeting of the Society of Tropical Medicine and Hygiene on Jan. 20th next.

## A VIEW OF THE HOUSING AND TOWN PLANNING ACT.[1]

Dr. Thresh has made, we believe, the first report under the conditions imposed on the rural district councils by the Housing and Town Planning Act, and takes therein the occasion to make some pertinent remarks on the working out of that Act. He lays down various conditions as essential to a healthy house and discusses them in detail. With regard to the inspections ordered by the Local Government Board these are so much more exhaustive than heretofore that if the medical officer of health is to make them it will be necessary to appoint to that office only one who can give his entire time to his duties, and there will be plenty to keep him fully employed; if, on the other hand, the inspector is to add this duty to those already incumbent on him before the passage of the Act it will be necessary for him to have assistance in the enormous amount of clerical work involved. The author's experience leads him to the conclusion that the Act will not only benefit the working classes by greatly improving housing conditions in all rural districts, but by raising the sanitary standard will benefit all classes of residents also.

## ENLARGEMENT OF THE SUPERFICIAL THORACIC GLANDS AS A SIGN OF PULMONARY TUBERCULOSIS.

MANY clinicians have called attention to an enlargement of the lymphatic glands which lie beneath the skin of the thorax in relation to the fourth and fifth intercostal space in the mid-axillary line, and which can be felt and sometimes seen in a certain percentage of cases of pulmonary and pleural tuberculosis. E. v. Zebrowski[2] has recently brought forward figures to show that in about 20 per cent. of adults afflicted with this disease an enlargement in these glands can be detected. W. Schulze[3] confirms this observation, though the percentage was somewhat lower in his cases, but at the same time he publishes notes of a case which seem to show that this cannot be relied on as a sign of tuberculosis as opposed to other pulmonary disorders. The patient, a boy aged 7 years, came under treatment for pyrexia with vomiting. The pulse-rate was 160 per minute, the respiration-rate 48, and the temperature over 105° F. By the usual methods of examination no physical signs of pulmonary disease were found, but skiagraphy discovered a shadow over the whole right pulmonary area, especially in the neighbourhood of the upper lobe. For three weeks the fever followed an irregularly hectic course, but the tuberculin test, applied by Moro's method, was negative. The axillary and inguinal glands were enlarged, and there was a gland about the size of a pea in the fifth right intercostal space near the mid-axillary line. Under local anæsthesia this was excised; half was examined histologically and the other half injected into the peritoneal cavity of a guinea-pig, but by neither means was any evidence of tuberculosis forthcoming. After remaining above normal for five weeks the temperature gradually fell, the other symptoms disappeared, and the X ray shadow was no longer to be seen. The case must therefore be regarded, in Schulze's opinion, as one of central pneumonia running an atypical course, though at first it seemed likely to prove tuberculous; and he brings it forward as evidence that tuberculosis is not the only infection of the lung which leads to enlargement of the lymph glands beneath the skin of the thorax.

[1] Report of the Housing of the Working Classes in Ingatestone. By John C. Thresh, M.D Vict. Chelmsford: John Dutton. 1910.
[2] Deutsche Medizinische Wochenschrift, 1910, No. 28.
[3] Münchener Medizinische Wochenschrift, 1910, No. 51.

WE publish on p. 77 of this issue of THE LANCET the address with which Dr. T. B. Hyslop, late resident physician at Bethlem Hospital and President of the Society for the Study of Inebriety, opened a debate in that society on Tuesday last on the Influence of Parental Alcoholism on the Physique and Ability of Offspring. No representative of the Eugenics Society was present at the meeting, a fact commented upon by Sir Victor Horsley in promising to draw attention in the immediate future to Professor Karl Pearson's startling conclusions. Mrs. Scharlieb, Dr. C. W. Saleeby, Dr. W. C. Sullivan, Dr. E. Claude Taylor, Canon Horsley, and Mr. Theodore Neild also took part in the discussion.

THE Hunterian Oration of the Royal College of Surgeons of England will be delivered by Mr. Edmund Owen in the theatre of the College on Tuesday, Feb. 14th, at 4 P.M. The President and Council will give a dinner at the College the same evening.

## THE NEW GERMAN PHARMACOPŒIA.

THE new edition of the German Pharmacopœia—the fifth since the creation of the empire—has now been issued, and in many respects it presents an entire departure from the usual attitude adopted by its authors. It may be mentioned that now this work is elaborated by a special Commission of the Imperial Sanitary Council, composed of 26 members, including Government medical officers of health representing the more important German states, professors of pharmaceutical chemistry, botany, chemistry and pharmacognosy, and a number of pharmacists in business. In addition to the above, representatives of clinical medicine, veterinary surgery, bacteriology, the Patent Office, the War Office, and others were called upon to attend the meetings of the Commission, and in order to have a true picture of the materia medica at present in use in prescription work a circular was issued by the governments to 125 of the larger town and country pharmacies asking for information as to the frequency with which official preparations occurred on prescriptions, and also concerning older non-official articles. It must be remembered that in Germany practitioners are forbidden to dispense their own prescriptions, hence this step to establish the degree of popularity of various remedies.

The new Pharmacopœia has been most thoroughly revised, and its chemical as well as microscopical methods of analysis of chemicals and vegetable drugs speak most favourably for the high standard of scientific training of the German pharmacist. The microscopic analysis of drugs has been most minutely described, the dimensions of cells being indicated in micro-millimetres, and an estimation of the active principles is prescribed in almost every instance in the case of the more important drugs. It is interesting to note that the Commission distinctly states in the preface to the volume that it had been decided to make this book more useful to the physician by the addition of a certain amount of information not otherwise incorporated in the Pharmacopœia. This departure from the traditions of the *Pharmacopœia Germanica* has been effected by the inclusion of references to the content of active ingredients in each official substance, and of the impurities to be revealed by the application of each prescribed test, so that the reader can at a glance judge of the strength and purity of any given substance. Thus, we read that sodium bromide contains 94·3 per cent. of NaBr, or 73·2 per cent. of bromine; atoxyl, 24·1 to 24·6 per cent. of arsenic; iron and quinine citrate, 9 to 10 per cent.

quinine and 21 per cent. iron; sodium carbonate contains at least 37·1 per cent. of anhydrous $Na_2CO_3$; cinchona bark at least 6·5 per cent. of quinine and cinchonidine; while in the case of nux vomica not the content of strychnine alone is assayed for, but a mixture of the two principal alkaloids—strychnine and brucine.

Among the changes introduced in the formulæ of galenical preparations we note the use of arachis oil instead of olive oil in a number of liniments, and of soft paraffin in the place of paraffin ointment in several ointments. The additions to the present edition constitute no less than one-eighth of the total 671 monographs. Considerable surprise has been caused by the method adopted with regard to the inclusion of the newer synthetic remedies, of which 20 have been included. It has hitherto been the custom of the authors to totally ignore the protected name of such preparations, and therefore the full chemical designations were adopted in the last edition—viz., "pyrazolonum phenyldimethylicum salicylicum" for salipyrin. It has been recognised that such a course is in many instances not consistent with practical everyday requirements, and therefore in the case of exceptionally long chemical names (such as is the case with novocaine, pyramidon, and stovaine) the registered appellation has been adopted as the title, followed by the scientific name; and in other cases—e.g., acidum acetylosalicylicum, acid. diæthylbarbituricum, æthylmorphinum hydrochloricum—where the chemical name is not too unwieldy, the latter figures as the title, followed by the registered designation as a sub-title (in the above examples: aspirin, veronal, dionin). It is, however, distinctly stated that the question of dispensing such preparations must take place in accordance with the provisions of the law on registered trade marks; both protected product and its "substitute" must correspond to the tests laid down in the Pharmacopœia. We see that in this instance the authorities—the volume receives the sanction of the Federal Council and is enforced by the Imperial Chancellor—have not hesitated to dictate to the manufacturers of protected products included in the Pharmacopœia the degree of purity that the latter must possess, a step that is bound to call forth considerable comment.

The following potent drugs have been added to the Pharmacopœia with the stated maximum doses. It may be remarked that the latter also apply to the dispensing of the substance in the shape of eye lotions, hypodermic injections, clysters, suppositories, and inhalations:—

| | Maximum single dose. | Maximum amount during 24 hours. |
|---|---|---|
| Arsacetin | 3 grains. | — |
| Atoxyl | 3 ,, | — |
| Dionin | ½ grain. | 1½ grains. |
| Duotal | 15 grains. | 45 ,, |
| Heroin hydrochloride | 1-12 grain. | ¼ grain. |
| Lactophenin | 8 grains. | 45 grains. |
| Pyramidon | 8 ,, | 24 ,, |
| Scopolamine hydrobromide | 1-120 grain. | 1-40 grain. |
| Suprarenin hydrochloride | 1-64 ,, | — |
| Theophylline | 8 grains. | 24 grains. |
| Urotropin | 15 ,, | 45 ,, |
| Veronal | 12 ,, | 24 ,, |

In addition to the above preparations we note the inclusion, among others, of aspirin, ethyl chloride, anæsthesin, colloidal silver (collargol), sodium nitrite, physiological saline solution (to be dispensed sterilised), protargol, cortex simarubæ, eucaine B., liq. aluminii acetico-tartarici, novocaine, ol. arachis., ol. sesami, pasta zinci salicylata, medicated soaps, antitetanic serum, stovaine, tannalbin, tannigen, tannoform, tropacocaine hydrochloride, ung. argent. colloïdalis.

Among the articles which have been dismissed figure: acid. hydrobrom., aqua picis, fol. jaborandi, fol. nicotianæ, fruct. papaveris immaturi, herba conii, lithium salicylicum, vin. colchici, and vin. ipecacuanhæ.

An interesting addition to the present edition has been made in the inclusion among the appendices of a list of formulæ and reagents for preparing tests employed in biological analyses. These include the reagents used in demonstrating the presence of pathological substances in urine, such as albumin, sugar, pentoses, acetone, aceto-acetic acid, urobilin, urobilinogen, bile pigments, indican, iodine, salicylic acid, blood, and for applying the diazo reaction; further, the reagents for testing stomach contents and blood; stains for bacteriological work; and, lastly, a description of cedar oil, canada balsam, and xylol for use as microscopic mounts.

In the article on suprarenin hydrochloride, which bears the chemical name o-dioxyphenyl-ethanolmethylamino-hydrochloride, it is described as the hydrochloride of the vaso-constrictor substance of the suprarenal gland, and is either prepared from the latter or obtained synthetically; it is marketed under the names adrenalin, paranephrin, epinephrin, and epirenan in the shape of sterilised solutions to which a preservative has been added. It is forbidden to dispense solutions which are coloured red or have become cloudy.

In view of the expected new edition of the British Pharmacopœia the above work should prove of special interest to those entrusted with the elaboration of our Imperial Pharmacopœia. It only remains to be seen to what extent the stringent scientific and practical requirements of the German volume are compatible with actual conditions.

## MEASURES FOR THE REDUCTION OF INFANTILE MORTALITY IN BAVARIA.

IN a Bavarian Ministerial Circular, dated Dec. 9th, 1907, certain general principles were outlined for the control of infantile mortality. The Central Department for Infant Care (Imperial Health Office of Germany), as the result of accumulated experience, has partly reconstructed and partly reaffirmed these principles, and in an order of the Minister of State for Internal Affairs, dated Jan. 20th, 1910, and addressed to the Royal Government, officers for home affairs, district and parochial boards, and district physicians, the department has suggested suitable rules and regulations. It has been found impossible to go into detail upon every matter owing to the differences caused by local conditions, the amount of money at the disposal of the boards, the density of population, facilities for transit, economic conditions, and method of livelihood of the people, &c., but certain guiding principles have been laid down. In purely rural districts it is recommended that the work of infant care, in conjunction with the conscientious superintendence of the "boarding-out system," should be confined to careful arrangement for guardianship, and the carrying out of enactments for the protection of mothers, supplemented by continuous popular instruction both verbal and written, a work in which clergymen, physicians, and midwives should be induced to take an active part. In large communities where various associations take a share in the work of infant protection the creation of a local central department is recommended which would coördinate separate efforts. The business of such a "care association" should be to support poor lying-in mothers and to seek out and advise pregnant single women, to establish dispensaries under medical supervision and in connexion with them, milk depôts, and crèches where women could go to suckle their children.

Infant care is considered under the headings "Unrestricted" and "Restricted," the latter referring to measures and institutions for the benefit of children whose parents are not necessitous. The institutions are to be regarded as belonging to the class of working-men's benefit institutions, and should be worked in conjunction with other schemes which are carried on for the benefit of the local working-class population, whether voluntary or municipal. Such agencies are philanthropic guilds, municipalities, and the larger manufactories. Contributions for their working are provided out of State funds for infant care or the surplus of State insurance societies.

### *Instruction.*

The spread of the knowledge of rational infant care—e.g., the necessity of breast-feeding wherever possible and what constitutes a suitable food for infants that are artificially fed—is regarded as at least a collateral aim in all establishments for infant care, and to this end leaflets on infant care are to be distributed among the people by the registrars of births, midwives, foundling nurses, and by physicians at lectures, crèches, and advisory dispensaries. In this matter assistance is given by the Women's Red Cross Association of Bavaria. In addition

to these a special periodical is edited and sold by the central department, containing popular and scientific articles, from which the local press are desired to print extracts so as to obtain for them a wider publicity than would otherwise be assured; and occasion is taken to recommend approved books on infant care and rearing to mothers. Lectures by physicians and properly trained women are also given, and it is satisfactory to note that lectures on artificial feeding are not to be given except by medical men. This is only one instance of that prudence and subordination to expert medical opinion and advice which characterises all the measures taken by the Bavarian Government for the prevention of infantile mortality.

*Consultation Centres, Contributions, and Premiums.*

Consultation centres are established under the control of physicians, where mothers will obtain advice, free of charge, on the care of healthy and sick infants. Infants are superintended outside the consultation centres in small districts by members of the Women's Guild, and in larger districts by paid female health visitors. Premiums for breast-feeding are paid to mothers to compensate them for loss of working time entailed by breast-feeding, and midwives are also given rewards who show good work in inducing mothers to feed their infants at the breast. The care of the finances of these consultation centres, and especially the granting of breast-feeding premiums, is in the hands of an administrative committee of which the superintending physician must be a member. Contributions are to be given only by the order and with the consent of the district physician, and where possible in the consultation rooms. In cases where the granting of support is in the hands of a committee which does not include the physician, his recommendation of applicants is necessary, and he is to be made acquainted with the grounds of refusal in any case recommended by him which is refused by the committee. As a rule, inquiries as to the worthiness of the parent to receive support are not made, for the aim is to save the infant's life. On the same grounds, no distinction is made between legitimate and illegitimate children. In certain cases, as, for example, when the mother is an alcoholic, premiums are given in kind instead of in coin. Necessary inquiries as to the means of parents, and especially of single mothers, are conducted with forbearance, and there are no fixed limits of income, disentitling applicants to support, discretion in these matters being allowed the physician.

In connexion with consultation centres are milk kitchens, which are intended to supply infants with milk as near in composition as possible to mother's milk. They are, of course, under medical supervision, and nourishment for sucklings is given on any physician's prescription, fixed formulæ being discouraged, as each individual case may require a different prescription. Milk is, as a rule, only given upon payment, which in the case of needy parents is made by parish authorities or philanthropic agencies upon a ticket system. As a rule, the cost of these kitchens is covered by the receipts, but if there is a deficit to be made up it is supplied from public sources.

*Restricted Infant Care.*

Crèches take in children for payment, during the first three years of life, without consideration of religion or parentage. The payment demanded is not to exceed the cost of nourishment. The children are under the charge of nurses, one nurse to six infants or 20 older children. For the housework servants are engaged. Special attention is paid to the quality and composition of the food for the children, and opportunity is given to mothers to breast-feed in the crèche and special terms are accorded to such mothers. Artificial feeding of infants is only to be undertaken upon a physician's prescription and certificate, and arrangements are to be made for supplying meals to artificially fed children at their homes during Sundays and holidays. Complete precautions against the introduction and spread of infectious diseases are taken and isolation and observation wards provided.

*Hospitals and Homes.*

These institutions receive and care for infants whose life is in danger through want or illness, and specially receive abandoned children. In urgent cases children are taken in without consideration of religion or parentage, but in other cases the identity of the child is to be ascertained and payment made beforehand. Arrangements exist for taking in a limited number of breast-feeding mothers, so as to have a supply of breast milk for the infants in case of need. The hospitals are also used as places for the education of nurses for infants and children.

Other measures directed to the same end—the prevention of infantile mortality—are concerned with the protection and assistance of women during the later months of pregnancy and during and after confinement. In this matter the aid of philanthropic associations and provident benefit societies is given, and lying-in hospitals and after-care homes have been established. The care of abandoned and illegimate children is undertaken by guardianship courts exercising their powers under recent enactments, who provide suitable foster-parents for the children and care for their future.

# Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

*City of Newcastle.*—Typhus fever is now so rare in this country that the occasional outbreaks which occur are of considerable interest. Defective diagnosis is nearly always responsible for those outbreaks, and in the absence of any typhus fever for educational purposes the difficulty of diagnosis is obviously very great. In this instance there were removed to the isolation hospital at the end of November, 1909, five cases of what were supposed to be enteric fever, but which on admission were found to be suffering from typhus fever. Later the remaining member of the family—the mother—was removed suffering from the same disease. These cases were thought to have been infected indirectly from a case of supposed double pneumonia, and a young woman who nursed the case was afterwards sent to the hospital with scarlet fever. But in addition to what was supposed to be a scarlet fever eruption the girl showed indefinite symptoms which were believed to have been those of typhus fever, and on Dec. 16th a sister of this young woman was found recovering from supposed pneumonia, but which was probably typhus fever. Subsequently, and notwithstanding the disinfection of the house and effects, the remainder of the family were found to be ill with typhus fever on Jan. 3rd. There were 30 contacts connected with the above cases who were kept under observation, but none of them developed the disease in question. Dr. Henry E. Armstrong reports that as there was no smallpox during the year the buildings intended for this disease were used for scarlet fever convalescents. During the twelve months ended Nov. 26th, 1909, there were 64 corporation patients from Newcastle admitted into the Barrasford Sanatorium for Consumption. A table is furnished in the appendix to the report dealing with each case, but it is not clear from this what are the dates at which the observations relative to the after-histories of the cases were made. Presumably they relate to the condition on discharge, but this is not as clear as it might be, and we venture to hope that in the next annual report the after-histories of the patients discharged during 1909 and 1910 will be furnished, those for each year being kept separate and the dates of the last observation being also entered.

*County Borough of Derby.*—Dr. Albert E Brindley, in dealing with the history of diphtheria in Derby, shows by means of a tabular statement the fatality rate of this disease from 1881 onwards. It is interesting to observe the manner in which the case incidence per 1000 of the population has more or less steadily increased, although, of course, the questions of improved diagnosis and better notification have a very great influence in this direction. The case incidence in 1881 was 0·08 per 1000, in 1891 0·71 per 1000, in 1901 0·70 per 1000, and in 1909 5·04 per 1000. The case mortality has oscillated very materially. In 1883 it was only recorded at 15 per cent., but in 1886 it reached 33·5 per cent., and in 1889 41·4 per cent. In 1903 its first marked drop occurred to 3·6 per cent., and during the two years 1908 and 1909 it was 5·5 per cent. and 5·0 per cent. respectively. In connexion with treatment, it appears that in 1909 in the majority of cases admitted into the hospital antitoxin had not been previously given. As regards pulmonary tuberculosis, a list is furnished dealing with the question of causation, and the most interesting point is the very large number of cases which commenced after illness, suggesting, perhaps, not so much infection as the reduction in soil

resistance leading to the development of hitherto latent tuberculosis. The medical officer of health, who was for two years resident at the Royal Infirmary at Manchester, found that there nearly 40 per cent. of the post-mortem examinations—i.e., cases which had died from other diseases—showed evidence of former tuberculosis. These cases were, he observes, cured naturally.

*County Borough of Halifax.*—Dr. J. T. Neech estimates the population of this town at 107,750, as against an estimate of 111,911 by the Registrar-General, and the rates are based upon the former estimate. The birth-rate of the district is falling more rapidly than the death-rate, and during 1909 the excess of births over deaths was the lowest on record. The illegitimate birth-rate has manifested during recent years an increase in relation to the total births, this percentage now amounting to 4·8. There were 104 stillborn children buried during the year, and in one case where a child born alive was buried as stillborn the Registrar-General ordered the sexton concerned in the case to be prosecuted, and a fine was inflicted. The general death-rate of the district for the year 1909 was 14·4 per 1000, as compared with rates of 14·1, 15·1, and 14·5 for Leeds, Sheffield, and Bradford respectively. The infantile mortality was only 99 per 1000 births. As regards enteric fever, it was found that in 1908 20 per cent. of the cases were associated with the consumption of shellfish, but the "scare" connected with these cases produced such a falling-off in the consumption of this food that in 1909 only 6 per cent. of the total were regarded as shellfish-borne. In discussing the behaviour of diphtheria, Dr. Neech expresses the opinion that hospital isolation does not appear of much value in curtailing its spread. The case mortality for 1909 was 21 per cent. It would be very instructive if, with reference to each fatal case, the dates of attack and of the administration of antitoxin could in future be published in the annual report. This would be of use educationally, and tend to emphasise the value of antitoxin in the minds of the public. The water-supply of this borough is derived from upland surfaces, and for the most part there is no filtration. But as regards the water of certain reservoirs mechanical filters are employed. A table showing the percentage purification bacteriologically from these filters would be instructive. All the water apparently possesses some plumbo-solvent power, and one grain of slaked Buxton lime is added to each gallon of water as milk of lime, except in the case of one source which is very acid, and to this 8 grains per gallon are added, as well as ½ grain per gallon of albumin-juice for clarifying purposes.

*The City of Chester.*—Dr. J. R. Currie furnishes an instructive table as to the fatality-rate of scarlet fever in Chester from the year 1886 down to the present time. In 1886 the fatality-rate was 14·2 per cent. and in 1889 12·2 per cent. Since that time this fatality-rate has been falling in an irregular fashion, but in 1904 a rate of 10·9 per cent. was recorded, which, of course, was very high for such a recent date. In 1906 there were 102 cases without a death. There were two cases of human anthrax in Chester during 1909 and both proved fatal; one was that of a warehouseman and the other a butcher. In the first case the patient was not seen by a medical man until after death, and in the second the disease was recognised, but the man died shortly afterwards. He apparently contracted the diseased by inoculating himself with the flesh of a cow which had been slaughtered because it was dying.

*County Borough of Huddersfield.*—Dr. S G. Moore, who estimates the population of this district for the year 1909 at 103,000, reports that use has been made of a wooden pavilion in the grounds of the isolation hospital, which was originally intended for small-pox, for the education and treatment of early cases of pulmonary tuberculosis. Only carefully selected males are admitted, and preference is given to young adult wage-earners. The accommodation available does not enable the cases to be retained for more than from six to eight weeks, but during this time they learn how to live healthy lives, and the opportunity is taken to disinfect their dwellings. During 1909 there were five non-registered midwives practising in Huddersfield, but they appear only to have attended a few emergency cases. They were warned not to practise after April, 1910 The Huddersfield midwives alone attended, during 1909, 707 out of a total 995 cases, and during that year only 5 deaths occurred in the midwives' practice: 3 from puerperal fever, 1 from eclampsia, and 1 from pelvic cellulitis.

# VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8326 births and 4711 deaths were registered during the week ending Jan. 7th. The annual rate of mortality in these towns, which had declined in the five preceding weeks from 18·1 to 14·1 per 1000, slightly increased to 14·3 in the week under notice. During the 13 weeks of last quarter the death-rates in these towns averaged 14·7 per 1000, against 14·8 and 14·3 in the corresponding quarters of 1908 and 1909. In London the annual death-rate last quarter was equal to 15·3 per 1000, against 13·7 and 13·5 in the two preceding corresponding quarters. The annual death-rates in the 77 towns during the week under notice ranged from 4·2 in King's Norton, 6·7 in Hornsey, 6·8 in Ipswich, and 7·6 in Walsall, to 19·3 in Grimsby and in Dewsbury, 19·4 in Oldham, 20·4 in Bootle, and 21·0 in Swansea. The 4711 deaths from all causes in the 77 towns last week showed an increase of 120 upon the number in the previous week, and included 160 which were referred to measles, 76 to diphtheria, 57 of infants under two years of age to diarrhœa and enteritis, 53 to whooping-cough, 24 to enteric fever, and 22 to scarlet fever, but not one to small-pox; thus 392 deaths resulted from these principal epidemic diseases, against 442 and 391 in the two preceding weeks. The deaths from measles, which had been 208 and 185 in the two previous weeks, further declined last week to 160, but showed annual rates exceeding 2·0 per 1000 in Dewsbury, Middlesbrough, Bury, and Coventry. The fatal cases of diphtheria rose last week to 76 from 56 and 55 in the two preceding weeks; 20 occurred in London and its suburban districts, 5 in Portsmouth, 4 in Liverpool, 7 in Leeds, and 3 each in Birmingham, Bradford, and Cardiff. The 57 deaths of infants aged under two years attributed to diarrhœa and enteritis included 19 in London and its suburban districts, 7 in Liverpool, and 5 in Manchester and Salford. The deaths from whooping-cough, which had been 61 and 54 in the two preceding weeks, were 53 last week, of which 21 were returned in London and its suburban districts, 3 in Bristol, and 2 each in Brighton, Nottingham, Stockport, Manchester, Bradford, Leeds, Middlesbrough, and Newcastle-on-Tyne. The 24 deaths referred to enteric fever were within one of the number in the previous week, including 8 in London and its suburban districts, 4 in Manchester and Salford, and 2 in Wigan. The fatal cases of scarlet fever, which had declined from 30 to 21 in the four preceding weeks, were 22 last week, of which 3 occurred in Manchester and Salford, 3 in London and its suburban districts, and 2 each in Birmingham, Liverpool, and Cardiff. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily declined in the eight preceding weeks from 1882 to 1594, had further fallen to 1491 on Saturday last; 154 new cases of this disease were admitted to these hospitals during the week, against 167 and 140 in the two previous weeks. The 1328 deaths from all causes in London in the week under notice included 289 which were referred to diseases of the respiratory system, against 261 and 263 in the two preceding weeks. In the 77 large towns 180 deaths resulted from different forms of violence, against 179 and 186 in the two previous weeks; and 431 inquest cases were registered. The causes of 48, or 1·0 per cent., of the deaths registered during the week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, Nottingham, Leicester, Salford, and in 47 other smaller towns; the 48 uncertified causes of death in the 77 towns in the week under notice included 12 in Liverpool, 5 in Birmingham, 4 in Sheffield, 4 in South Shields, and 3 in Barrow-in-Furness.

## HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 817 births and 526 deaths were registered during the week ending Jan. 7th. The annual rate of mortality in these towns, which had been equal to 13·4 and 14·7 per 1000 in the two previous weeks, declined again to 14·3 in the week under notice. During the 13 weeks of last quarter the death-rates in these towns averaged 14·8 per 1000, only slightly exceeding the mean rate during the same period in the 77 English towns which

was 14·7 per 1000. The annual death-rates during last week in the eight Scotch towns ranged from 9·7 and 11·3 in Perth and Greenock to 16·5 in Dundee and 19·0 in Leith. The 526 deaths from all causes in the eight towns last week were fewer by 8 than the number in the previous week, and included 56 which were referred to the principal epidemic diseases, against 40 and 43 in the two preceding weeks; these 56 deaths were equal to an annual rate of 1·5 per 1000, and ranged upwards to 4·2 in Leith. Of these 56 deaths, 20 resulted from whooping-cough, 14 from diphtheria and croup, 12 of infants under the age of two years from diarrhœa, 6 from scarlet fever, and 2 each from measles and enteric fever, but not one from small-pox. The fatal cases of whooping-cough, which had been 12 and 7 in the two preceding weeks, increased to 20 in the week under notice, of which 7 occurred in Glasgow, 6 in Leith, and 3 both in Edinburgh and Dundee. Of the 14 deaths from diphtheria and croup, 6 were recorded in Glasgow and 5 in Edinburgh. The 12 fatal cases of infantile diarrhœa included 9 in Glasgow and 2 in Aberdeen. The 6 deaths from scarlet fever corresponded with the number in the previous week, including 2 in Glasgow. The 2 deaths referred to enteric fever occurred in Glasgow and the 2 fatal cases of measles in Edinburgh. The deaths referred in the eight towns to diseases of the respiratory system, which had declined in the five preceding weeks from 157 to 92, rose again last week to 98, but were 74 below the number returned in the corresponding week of last year. The deaths resulting from different forms of violence in the eight towns were 19 last week, against 15 and 17 in the two preceding weeks; and 151, or 29 per cent., occurred in public institutions. The causes of 11, or 2·1 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 largest English towns the proportion of uncertified causes of death last week did not exceed 1·0 per cent.

### HEALTH OF IRISH TOWNS.

In Dublin 203 births and 168 deaths were registered during the week ending Jan. 7th. The annual rate of mortality in the city, which had been equal to 21·6 and 18·9 per 1000 in the two preceding weeks, rose again to 21·5 in the week under notice. During the 13 weeks of last quarter the annual death-rate in the city averaged 19·8 per 1000, whereas in London the death-rate during the same period did not exceed 15·3 per 1000. The 168 deaths from all causes in Dublin last week showed an increase of 22 upon the number in the previous week, and included 19 which were referred to the principal epidemic diseases, of which 6 resulted from whooping-cough, 5 from scarlet fever, 4 from measles, 3 of infants under two years of age from diarrhœa or dysentery, and 1 from diphtheria, but not one either from small-pox or enteric fever. The 6 fatal cases of whooping-cough were fewer by one than those returned in the previous week; whereas the deaths both from scarlet fever and measles showed an increase. The deaths from all causes included 56, or 33 per cent., which were recorded in public institutions. The causes of 4, or 2·4 per cent., of the deaths in the city during the week were not certified either by a registered medical practitioner or by a coroner. In Belfast 241 births and 122 deaths were registered during the week under notice. The annual rate of mortality in this city, which had declined in the four preceding weeks from 20·1 to 12·1 per 1000, rose again last week to 16·0. During the 13 weeks of last quarter the annual death-rate in Belfast averaged 16·0 per 1000, against 19·8 in Dublin during the same period. The 122 deaths from all causes in this city during last week included only 4 from the principal epidemic diseases—namely, 3 from diarrhœa, enteritis, or dysentery, and a fatal case of scarlet fever; no death being referred to measles, diphtheria, whooping-cough, enteric fever, or small-pox. Six deaths resulted from different forms of violence; and 32, or 26 per cent., of the deaths occurred in public institutions. The causes of 3, or 2·5 per cent., of the registered deaths were not certified either by a registered medical practitioner or by a coroner.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—The King has sent his annual subscription of £1000 to King Edward's Hospital Fund for London.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeon E. Sutton to the *Highflyer*, on completing. Staff-Surgeons: P. F. Alderson to Chatham Dockyard; E. R. L. Thomas to the *Sphinx*, additional, and on recommissioning; and J. Boyan to the *Edgar*, and to the *Pegasus* on recommissioning. Surgeons: W. C. Carson to the *Pelorus*, and to the *Merlin* on recommissioning; G. A. S. Hamilton to the *Excellent*, additional, for the *Revenge*; L. C. Hunt, to the *Blenheim*, additional for the *Swift*; C. F. O. Sankey, to the *Temeraire*; R. J. G. Parnell to the *Highflyer*, on completing; P. B. Egan to the *Skipjack*; E. MacEwan to the *Africa*; A. H. Joy to the *Bulwark*, additional; and D. A. Mitchell to the *Argonaut*, and for group of ships of Fourth Division Home Fleet; F. C. Robinson to the *Edgar*, and to the *Sealark* on recommissioning; and C. J. Aveling to the *Edgar*, and to the *Fantome* on recommissioning.

### ROYAL ARMY MEDICAL CORPS.

Colonel W. G. Macpherson, C.M.G., has been transferred from Malta to India. Colonel F. B. Maclean has taken over duty as Principal Medical Officer of the Seventh (Meerut) Division on his return from leave. Lieutenant-Colonel G. H. Barefoot has been transferred from Bareilly to command the station hospital at Ranikhet. Lieutenant-Colonel J. J. Russell has been transferred from Limerick to the Southern Command. Lieutenant-Colonel H. H. Brown, from Murree, has been granted four months' general leave. Lieutenant-Colonel R. W. Wright, on arrival in India from England, has been selected to command the station hospital at Jhansi. Lieutenant-Colonel T. B. Winter, from command of the station hospital at Bareilly, has on arrival home been appointed Senior Medical Officer in charge of Recruiting Duties, London District. Lieutenant-Colonel C. T. Blackwell, from Woolwich, has taken over the command of the station hospital at Madras. Lieutenant-Colonel S. Glenn Allen has embarked for a tour of service at Gibraltar. Lieutenant-Colonel C. Birt has taken over command of the Fourteenth Company Royal Army Medical Corps at Dublin, in succession to Lieutenant-Colonel W. L. Reade, who has embarked for a tour of service at Mauritius. Major T. H. J. C. Goodwin, D.S.O., has been appointed Specialist in Advanced Operative Surgery to the Fourth (Quetta) Division. Major I. A. O. MacCarthy, on arrival home for duty from the Straits Settlements, has been posted to the Eastern Command. Major M. P. C. Holt, D.S.O., specialist in advanced operative surgery to the Third (Lahore) Division, has been transferred from Kasauli to Ambala. Major T. B. Black, from Aldershot, has taken up duty at Cairo. Major B. Forde, from Wynberg, has taken up duty at Bloemfontein. Major H. G. F. Stallard has embarked for a tour of service in India, for duty in the Seventh (Meerut) Divison. Major H. V. Prynne, from Gibraltar, has been posted to the Eastern Command. Major A. H. Waring, from Secunderabad, has taken up duty in the Southern Command. Major W. B. Winkfield has embarked in the troopship *Plassy* for India. Major W. E. Hudleston has been transferred from Golden Hill to Portsmouth. Major J. W. Jennings, D.S.O., Recruiting Medical Officer at Liverpool, has notified his intention to retire from the service on completion of 20 years' duty. Captain D. Ahern has taken up duty in Egypt. Captain F. A. McCammon has arrived home on leave from Quetta. Captain A. S. Williams has been transferred from Dinapore for duty at the station hospital, Dum Dum. Captain G. R. Paignton has arrived home on duty from Sierra Leone. The following officers have joined the Royal Army Medical College, London: Captain A. J. Hull from Dover, Captain N. D. Walker from the London District, and Captain C. C. Cumming from Queen Alexandra's Military Hospital, Millbank. Captain A. H. Jacob has arrived home from Gharial, Northern India, on leave. Captain J. E. Powell, from Bareilly, has been granted four months' leave on medical certificate. Lieutenant A. Hendry has been transferred from Mhow to Indore. Lieutenant S. S. Dykes, from Barry Camp, has joined at Edinburgh. Lieutenant E. C. Lambkin has been appointed for duty at Windsor. Lieutenant J. R. Hill, from Monmouth, has been posted to Pembroke Dock. Lieutenant A. S. M. Winder, from Donard Camp, has been transferred to the

Curragh. Lieutenant F. R. Laing and Lieutenant J. T. Simson, appointed on probation July 31st, 1909, and Jan. 28th, 1910, respectively, have been stationed at Aldershot.

INDIAN MEDICAL SERVICE.

"The King has approved of the following appointments:—To be Colonel: Lieutenant-Colonel John Adams Cunningham (dated Oct. 26th, 1910). To be Brevet-Colonel: Lieutenant-Colonel Johnston Shearer, C.B., D.S.O. (dated Nov. 11th, 1910).

The King has approved of the following retirements:—Brevet-Colonel Johnston Shearer, C.B., D.S.O. (dated Dec. 6th, 1910). Lieutenant-Colonel John Adolphus Burton (dated Dec. 6th, 1910). Lieutenant-Colonel George Ernest Fooks (dated Dec. 6th, 1910). Major Thomas Alfred Ollivant Langston (dated Dec. 12th, 1910).

Lieutenant-Colonel D. T. Lane, civil surgeon at Lahore, has been appointed Professor of Forensic Medicine and Toxicology at the Lahore Medical College, in succession to Lieutenant-Colonel H. Hendly, who has been placed on special duty at Rawal Pindi. Lieutenant-Colonel J. J. Pratt, civil surgeon of Lucknow, has been granted privilege leave combined with furlough for 18 months. Lieutenant-Colonel R. C. MacWatt, Bombay, has arrived home on leave. Major F. O'Kinealy has taken up duty as Surgeon on the Personal Staff of the Governor-General of India. The services of Major H. J. K. Bamfield, district plague medical officer at Ferozopore, have been replaced at the disposal of the Commander-in-Chief. Major F. D. S. Fayrer, on return from leave, has been appointed by the Foreign Department of the Government of India to be Civil Surgeon at Dera Ismail Khan. Major H. J. Walton has taken over his appointment as Civil Surgeon of Bulandshahr. The services of Major J. C. H. Leicester have been replaced at the disposal of the Bengal Government. Major J. L. Macrae has had his appointment as Civil Surgeon of Coorg confirmed. The services of Captain W. J. Collinson, on plague duty in the Punjab, have been replaced at the disposal of the Government of India in the Home Department. Captain L. Cook, officiating civil surgeon at Midapore, has been granted two years' combined leave home from India. Captain C. A. Gourlay has passed in Bengali by the colloquial test. Captain W. F. Brayne has been appointed to Rangoon for duty in connexion with the prevention of plague. Captain W. E. McKechnie has taken over duty as officiating Civil Surgeon at Etawah, United Provinces. Lieutenant T. J. C. Evans has been appointed Specialist in Advanced Operative Surgery to the Eighth (Lucknow) Division. Lieutenant G. T. Burke has been transferred from the officiating medical charge of the 48th Pioneers to the officiating medical charge of the 11th Rajputs at Fyzabad. Lieutenant L. H. L. Mackenzie has been attached to the 72nd Punjabis at Dera Ismail Khan.

ROYAL NAVAL VOLUNTEER RESERVE.

The undermentioned gentleman has been appointed Surgeon:—Charles Francis Alexander Hereford (dated Dec. 30th, 1910).

TERRITORIAL FORCE.

*Royal Army Medical Corps.*

*Attached to Units other than Medical Units.*—Captain James Middleton to be Major (dated Nov. 23rd, 1910).

THE TERRITORIAL DECORATION.

The King has been graciously pleased to confer the Territorial Decoration upon the undermentioned Officers of the Territorial Force who have been duly recommended under the terms of the Royal Warrant dated August 17th, 1908:—

*Royal Army Medical Corps.*

Major James Arthur Rigby, attached to the 2nd West Lancashire Brigade, Royal Field Artillery. Major Joseph Dallas Pratt, attached to the 4th (City of London) Battalion, The London Regiment (Royal Fusiliers).

DEATHS IN THE SERVICES.

Colonel Francis Howard, retired pay, late Army Medical Staff, on Jan. 2nd, at Bournemouth, aged 69 years. He joined the army as assistant surgeon in 1863, becoming surgeon in 1873, and surgeon-major in 1876. He served during the Afghan war in 1878–79 in medical charge of the 25th King's Own Borderers (medal), and in the Egyptian expedition, 1882 (medal and bronze star). He became brigade surgeon in 1888, ranking as lieutenant-colonel, and retired in 1893. For some time Colonel Howard acted as medical officer of the Recruiting Staff in the Home District, and after his retirement was employed at the War Office during the South African war. He was the author of a "Handbook of Medical Organisations of Foreign Armies," and made some interesting communications in our columns on the subject of varicocele.

ANTITYPHOID INOCULATION IN THE ARMY.

In view of the advanced stage reached in the system of inoculation of troops against enteric fever the Army Council has decided that the practice of attaching specially selected junior officers of the Royal Army Medical Corps to regiments proceeding abroad for the purpose of carrying out the injections is to be discontinued, and officers now attached to units for this purpose are to revert to general duty. The inoculation at home stations of troops proceeding abroad will continue to be carried out, and inoculations in commands abroad will also be continued under present arrangements.

At the end of last year the North Riding of Yorkshire Branch of the British Red Cross Society had registered ten voluntary aid detachments, and the registration of several other detachments is contemplated.

## CLEAN MILK.

*To the Editor of* THE LANCET.

SIR,—It is recognised on all sides that few matters are of greater importance in promoting the health of the nation than a pure milk-supply. Yet, unfortunately, milk is peculiarly susceptible and liable to contamination, not only while it is in the hands of the producer and retailer, but also as soon as it reaches the consumer. For want of due care in handling milk is frequently, as is well known, a potent factor in the dissemination of a number of serious diseases, and has great influence on infant mortality.

Since the inception of the National League for Physical Education and Improvement in 1905 the question of pure milk has occupied a prominent position in its programme, and a special committee of eminent experts has devoted much time to the problem. The league is now undertaking definite practical steps to deal effectively with the matter. Pending more adequate legislation than at present exists, it is hoped that this action will arouse the nation at large to a sense of its responsibility in the matter. The intention, briefly stated, is to instil into the minds of all concerned in the production and consumption of milk a knowledge of the simple rules required to ensure its purity and cleanliness.

Full details of the scheme, and of the standard leaflets on which it is based, will gladly be sent on application to the Secretary of the League, at 4, Tavistock-square, W.C.

We are, &c., for the National League for Physical Education and Improvement,

W. B. RIPON,
Chairman of the Executive Council.
F. MAURICE,
Maj.-Gen., Hon. Vice-Chairman.
LAUDER BRUNTON,
Vice-Chairman.
JOHN TWEEDY,
Vice-Chairman.

## THE CURRICULUM OF THE MEDICAL STUDENT.

*To the Editor of* THE LANCET.

SIR,—Sir Henry Morris's speech, reported in your issue of Jan. 7th, will, I trust, receive the close attention of every member of the profession. In my opinion no more mischievous proposal, for both the profession and the public, could be devised than that which he has put forward.

For a considerable time the profession has felt that the preliminary general education standard for students entering it has been allowed to reach a seriously low level as compared with the standards required by other professions. A few years ago it had become practically equivalent to the standards required of students of veterinary surgery and pharmaceutical chemistry. The matter was then considered by the British Medical Association, and as the result of a careful inquiry a deputation was sent to the General Medical Council to urge the necessity for considerable changes. The General Medical Council, however, found themselves unable to do anything to alter the existing state of affairs.

The reason for this will be naturally searched for by everyone interested in the matter. The financial interests of the licensing bodies and those of the profession at large are absolutely different. The profession is gravely overcrowded, and the proper way to correct this evil—as great an evil ultimately for the public as for the profession—is clearly to make the entrance standard of general education what can only be described as a commonly decent one. The licensing bodies collectively, on the other hand, have everything to gain from passing into the profession an excessive number of candidates, and, to them collectively, the establishment of a high standard of general education would obviously be a financial misfortune. The age-limit for entry into the profession has been fixed by the General Medical Council at 16 (!) and the standard of general education required at what is suitable to boys of a little over 15! Sir Henry Morris now proposes to shift into the school curriculum a portion of the professional studies! What the British Medical Association proposed was to raise the age-limit of entry to 17 and the standard to one suitable to boys of average intelligence at that age.[1] Now, let it be clearly grasped what Sir Henry's Morris's proposal means. It means a virtual lowering of the already too low age-limit. Not only so, it also means the reduction of the already all too short time which may be allotted to that general culture which makes so vast a difference to the man in after life, whatever his position may be. Further, it means, in some cases at all events, admitting boys into medical and surgical, male and female, wards at what I do not hesitate to call an indecent age. It is, in fact, a proposal for the further cheapening of the medical curriculum in no way calculated to elevate the character or improve the prospects of the profession, or to increase the confidence felt by the public in it and in its governing council.

I trust that the profession will not miss the real meaning of this most grave proposal, and will begin to consider whether the time has not come for a strong assertion of the right of medical men collectively to determine for themselves the standard of culture for the profession which public policy demands; for not leaving the sources of the profession's prosperity, efficiency, and prestige at the mercy of any official body, however exalted, which has financial interests so obviously irreconcilable with those of the profession generally.

I should be sorry to say a word which would belie the great respect I entertain for Sir Henry Morris personally. He is incapable of intentionally doing this great injury to the calling on which he himself reflects so much honour. But "evil is wrought for want of thought, as well as from want of heart." It is the system and the mode of thought, which can lead one so able and so well-intentioned to enunciate anything so pernicious, that I desire to call attention to. If the profession is so short-sighted as to allow this proposal to be carried into effect, the time is not far distant when it will have cause to regret a lamentable want of wisdom. I am, Sir, yours faithfully,

Exeter, Jan. 9th, 1911. W. GORDON.

## MENDELISM AND HEREDITARY CRANIO-CLEIDO-DYSOSTOSIS.

*To the Editor of* THE LANCET.

SIR,—Your issue of Nov. 19th, 1910, contained an able and outstanding paper by Mr. D. C. L. Fitzwilliams of St. Mary's Hospital on Hereditary Cranio-cleido-dysostosis. At the close of his communication he sums up as follows:—

> It might be suggested that the cause in both affections [hereditary cranio-cleido-dysostosis and achondroplasia] is due to the presence or absence of certain chemical constituents which are necessary for the correct ossification of membrane bones in the one case and of cartilage bones in the other; in much the same way as we know that hæmophilia must be due to a hereditary absence from, or presence in, the body of certain chemical constituents. Couvelaire advanced a somewhat similar view when he said that hereditary cranio-cleido-dysostosis was "the expression of a general taint with a predominance in certain osseous groups.[1]"

I hope you will give me some of your space for a few remarks on this condition in relation to Mendelism and the origin and maturation of the ovum.

As the author states, "hereditary cranio-cleido-dysostosis is a condition which affects those bones which develop wholly or partly in membrane." Professor Fawcett of Bristol points out in his interesting Long Fox lecture[2] on the Development of the Human Skull, the exact details, but for our purposes it may be stated that the cranial vault and the interparietal part of the occipital bone are laid down in membrane, and we must add to this the additional fact that the outer half of the clavicle, the earliest bone in the body to ossify, is also developed in the same basis. In one of his two cases (a child 3 years old) Mr. Fitzwilliams found that the deficient ossification affected the vault of the cranium and the interparietal occipital portion and the outer half of the clavicle. The basi-occipital ossified as usual in cartilage.

Expressed in Mendelism, this is a condition where we have a deficiency or loss to the organism, of the determinant for ossification in the definite group of unit-characters for the ossification of the bones laid down in membrane. Heredity plays a part in the history, as in 60 cases collected 31 came from eight families. The conditions as to heredity will be best studied, however, in brachydactyly, to be taken up shortly. In the condition known as achondroplasia to which the author alludes, we have a defect in length of the bones developing in early endochondral ossification—viz., the upper and lower limbs, the innominate bones, the ribs, and the basi-occipital; and from a Mendelian point of view we have here a loss of the determinants, in part, which govern the length of the bones developing in early endochondral ossification. Those in which later endochondral ossification occurs—the spine, carpus, tarsus, sternum, costal cartilages, patellæ—are unaffected, and the bones developing in membrane, as already stated, are normal. It is the change in the basi-occipital that gives the achondroplasic the skull alteration (see "Encyclopædia Medica," Vol. I., p. 55).

If now we take brachydactyly, where the middle phalanx of the fingers[3] is apparently awanting, we find that while the fingers have only two phalanges, the missing middle phalanx is represented by a nodule of cartilage ankylosed to the first phalanx (Drinkwater). This condition may be regarded then as a loss in the unit-character of length for the middle phalanges of the foot and hand. All these so-called deformities I regard as really variations and not as pathological conditions. We see, therefore, that in these three variations we have an exact loss, as exact as a brick out of a wall.

If, then, we grant that a Mendelian unit-character is lost, the question comes, Where has that occurred? The answer I suggest is this—that the loss occurred in the maturation of the germ- and sperm-cells prior to fertilisation, when the chromosomes are reduced to a half for each gamete. These reduced cells, now the gametes, unite in fertilisation and make up the normal number for the zygote (fertilised ovum). My reasons for adopting this hypothesis are that (1) the determinants of heredity are in the nucleus of the primitive germ- and sperm-cells; thus when these are reduced by the loss of the polar bodies we get some heredity determinants

[1] Op. cit., THE LANCET, p. 1475.
[2] Bristol Medico-Chirurgical Journal, June, 1910.
[3] The foot is similarly affected. In the Naegele pelvis, where there is some defect in the unit-character determining the size of one side of the pelvis, there is sacro-iliac ankylosis.

thrown off. The centrosome is generally held to regulate the division of the chromosomes, and the cytoplasm has not been shown to be directly concerned with heredity. If it be urged that the same chromosomes may be lost at each fertilisation, and that thus variation cannot result, the objection will be seen not to be valid when another question is considered. It is granted that heredity conditions are transmitted and that the same happens in the case of crossings of plants and animals. The question now arises, How is this? We must grasp here firmly a disputed fact—viz., that the primitive germ- and sperm-cells in the ovary and testis respectively, from which the gametes arise, are not derived from the germ and sperm epithelium (Waldeyer's view in 1870), but arise from an early division of the early zygote, travel through the developing embryo, and ultimately become fixed in the genital ridge of the Wolffian body (Eigenmann, Beard, and others). They are then the primitive germ- and sperm-cells (ordinary ova and spermatozoa) and become gametes when the polar bodies are thrown off. Thus the gametes contain heredity determinants owing to this origin, while the view that the primitive germ- and sperm-cells are modified somatic cells makes heredity unintelligible.

The question of the ratios as in brachydactyly can be under explained only by Mendelism. Mendel showed that in plant crossings the contrasted unit-characters segregate out in such a manner that in the second and third generations, taken together, there is a ratio of 1 : 2 : 1 *in the plants*. Mendel thought that this was due to a combination of the pollen grains and egg-cells giving this elementary probability result, and as a plant was by him, unfortunately, considered as a merely somatic organism in which one does not require to recognise a propagative and somatic part a serious error was made. It was thus not recognised that the significance of the first generation following in its soma one of the contrasted unit-characters is that the 1 : 2 : 1 ratio in plants cannot be due to gametic combination seeing that the combination of egg-cells and pollen grains ends in a generation. The determinants of the contrasted unit-characters in crossings really segregate out in the zygote in the 1 : 2 : 1 ratio and that is the reason why biometric measurements of stature, &c., in man and plants give some form of this curve. When once we see that determinants re-arrange themselves in the zygote according to the curve of frequency we can extend this process to the primitive germ-cells and gametes.

I hold then that the significance of the mitotic changes in the primitive germ-cells of the early developing ovary is that these are producing variation of the determinants of heredity both by the gross divisions and by a minute re-arrangement in the divided particles. Thus all the determinants are re-arranged by the law of frequency and not by Galton's law, but this point would take too long to consider here. In this way we get in the polar bodies thrown off, not always the same determinants but different ones, and as important ones have their chance of loss, each unit-character gets thus its dangerous time of loss.

In brachydactyly Drinkwater found the ratio in families affected to be 50 per cent. affected, 50 per cent. non-affected. This is, I believe, explained if we suppose that the whole determinant for length for the middle phalanx was lost and thus it is like a head or tail result in tossing, 50 per cent. of each.

That the variations or deformities are *automatic* losses is emphasised by the fact that analogous conditions explainable on the same hypothesis—e.g., anencephaly, genital deformities, &c —are constantly occurring, although from their nature there is no heredity—such variations are incapable of propagation. The three deformities considered, cranio-cleido-dyostosis, achondroplasia, and brachydactyly, are thus due to a loss of the determinants of a Mendelian group of unit-characters at the maturation of the ovum or spermatozoon; they are transmitted because the primitive germ cells are derived from an early division of the zygote when the determinants are causal; and are transmitted with a probability result, because their determinants are re-arranged in the primitive germ-cells and zygote according to a frequency law. Ordinary variations arise in this way, but gross losses in the polar bodies will give a marked variation—a mutation, in fact.

I have trespassed too long on your space and therefore do not consider how far Darwinism could be applied, and I have also had to omit many details. I wish, however, to state in conclusion that I am confident the day will come when the body of man will be considered as made up of functional and anatomical unit-characters—i.e., of Mendelian autonomous units. In the skeleton we have three great groups already: (1) the bones developed in early endochondral ossification; (2) those in late endochondral ossification; and (3) those in membrane. In the brain and spinal cord we have the corpus callosum, which may be exactly wanting in some cases, the spinal cord, the spinal ganglia, posterior roots, and sensory nerves. In amyelia the first is absent but the others present (Oppenheim, Bruce's translation, p. 393). In the genital organs similar groups can be made, while albinism, hæmophilia, and many other structures or conditions yield to this generalisation and line of research. In tracing a family tree we may be able to plot out how these segregate, and ultimately reach the law governing this. Whichever mechanism is the successful one in explaining evolution mysteries, I do not believe that only *one* will succeed, but I hold that one of the most important will be that much criticised and much misunderstood Mendelism which has made the name of Mendel as immortal as those of Darwin and Wallace.

I am, Sir, yours faithfully,

Edinburgh, Jan. 7th, 1911. D. BERRY HART.

## THE BOARD OF TRADE COMMITTEE ON COLOUR VISION.

*To the Editor of* THE LANCET.

SIR,—I have been strongly advised to write to you with regard to the composition of the Colour Vision Committee appointed by the Board of Trade. Though the overwhelming majority of experts are on my side with regard to the extremely inefficient wool test used by the Board of Trade, not a single one of those who have been instrumental in bringing about the appointment of this committee is on it, whilst those who are definitely associated with the wool test very largely form its expert opinion. The president of the old committee that recommended the wool test is on the committee and the secretary is a physicist who employs the condemned method and is a strong advocate of the wool test. Twenty years ago I was appointed on the International Code of Signals Committee to advise the Board of Trade as to efficient tests for colour blindness. When the committee of the Royal Society (which, like the present committee, had a large majority of physicists, there being only one physiologist) recommended the Holmgren test, and that it was not necessary to have a medical man to test for vision and colour vision, my connexion with the Board of Trade ceased, my place being taken by a physicist, the secretary of the committee. Therefore, for this obviously medical duty the Board of Trade does not employ a single medical man.

Colour-blindness is a physiological subject, and a knowledge of physiology, psychology, and ophthalmology is necessary for its appreciation. One of the two physiologists appointed by the Board of Trade has, through illness, not been able to attend the meetings of the committee. I would suggest that the number of physiologists be made equal to the number of physicists. I have done everything in my power to help the committee to come to a correct conclusion, and shall continue to do so. They have, however, made this very difficult for me, as I wished to make it a condition that I should be present when they examined any of my colour-blind cases, men who are able to pass the Holmgren test. This they refused, so I withdrew the condition, but had they acceded this letter would never have been written.

I am, Sir, yours faithfully,

F. W. EDRIDGE-GREEN.

The Institute of Physiology, University College, London, Jan. 3rd, 1911.

## THE CHURCH ANTI-VIVISECTION LEAGUE.

*To the Editor of* THE LANCET.

SIR,—As I presume the circular issued by the Church Anti-Vivisection League has been sent broadcast to the profession, I thought it might interest your readers to see a copy of my reply to the secretary. I therefore inclose a copy, and hope that if you can find room for it in your journal it may help to prevent some of your readers, through

simple thoughtlessness, giving permission for their names to be added to the list in question.

I am, Sir, yours faithfully,

CHARLES W. HAYWARD,
Liverpool, Jan. 10th, 1911. Barrister-at-Law, M.D., D.P.H., &c.

[ENCLOSURE.]

To the Clerical Organising Sec. Church Anti-Vivisection Society.

DEAR SIR,—In reply to your circular asking me to allow you to add my name to a list of medical practitioners to be used by your league, I must emphatically decline to have my name included in such list.

I am as much against unnecessary cruelty to animals as anybody, but to entirely abolish the right to try the effects of drugs, &c., upon animals would restrict these experiments to being tried upon the human race, which is "out of the frying-pan into the fire!" The Anti-Vivisection Society publishes posters and literature showing that the sufferings of animals in any experiments are equal to similar proceedings with human beings. This is pure dishonesty, and for the purpose of trading upon the ignorance of the public, and raising violent prejudices founded entirely upon ignorant sentimentalism. Animals are saved the mental effects, which are the greater part of human suffering.

Your circular is also in very questionable taste. It asks for names of doctors—"not for publication"—and then offers a temptation to the meaner instincts by stating "we are often asked by Anti-Vivisectionists for the names of Anti-Vivisectionist doctors in their respective neighbourhoods"! Under these circumstances the allusion to "unconscious quackery" is humorous. Yours faithfully,

CHARLES W. HAYWARD,
Jan. 9th, 1911. Barrister-at-Law, M.D., D.P.H., &c.

## THE USE OF IODINE AS A DISINFECTANT OF THE SKIN BEFORE OPERATIONS.

*To the Editor of* THE LANCET.

SIR,—Will you permit me to inform Mr. Willmott Evans that he is in error in stating "the first advocate of its use in this country was Mr. H. F. Waterhouse." My original paper was published in the *British Medical Journal* on August 14th, 1909, several months before Mr. H. F. Waterhouse's communication. I there stated that Dr. A. Grossich of Fiume had used liquor iodi, 10 per cent. solution. So far as I am aware, I was the first surgeon to use tincture of iodine, 2½ per cent. solution. May I also point out that, as I have insisted, shaving is unnecessary and the colour of the iodine is an advantage because it shows the limits of its application.—I am, Sir, yours faithfully,

J. LIONEL STRETTON,
Senior Surgeon, Kidderminster Infirmary and
Jan. 9th, 1911. Children's Hospital.

## EHRLICH'S DIAZO REACTION.

*To the Editor of* THE LANCET.

SIR,—Some remarks in your review of "International Clinics" on p. 1881 of THE LANCET of Dec. 31st, 1910, remind me that I made a long series of experiments with Ehrlich's diazo reaction in various diseases during the early months of 1893. The article containing the results obtained appeared in the *Indian Medical Gazette* for June, 1893. The reaction was most marked in chronic diarrhœa and dysentery and was seen more or less in other diseases.

I am, Sir, yours faithfully,

J. H. TULL WALSH
Jan. 7th, 1911. Lieutenant-Colonel, I.M.S. (retired).

## A METHOD OF SERUM DIAGNOSIS FOR TUBERCLE.

*To the Editor of* THE LANCET.

SIR,—I was not aware that Dr. W. d'Este Emery was also working on this subject or I would have communicated with him before sending an account of my experiments to you. I had no previous knowledge of work on the subject, but followed the principles of the Bordet-Gengou reaction. Before completing the article I looked up "Hewlett's Bacteriology," and found the statement that Wassermann and Brück had experimented on this subject in 1906, and that they appear to have failed to find tuberculous antibodies in localised or latent tuberculosis, but that Brück had been more successful with acute miliary tuberculosis in the early stages. By the method I described these antibodies can be clearly shown to exist in localised tubercle.

The first point Dr. Emery raises is the standardisation of the fresh tubercle emulsion. My procedure has been to prepare an emulsion on the lines employed for the "opsonic index." I gauge the strength by the appearance. This gives a rough but working standard. I do not find that standardisation of the emulsion is of such extreme importance, for I have obtained equally satisfactory results when employing 5 c.mm., 10 c.mm., and 20 c.mm. of the same emulsion, with 10 c.mm. of unheated and 40 c.mm. of heated serum. But I fully agree with Dr. Emery that there comes a point when, through an excess of the tubercle emulsion, normal human serum loses its power of hæmolysing sheep's corpuscles (probably due to fixation of the complement).

Dr. Emery states that 1/500th dilution of his emulsion fixed the complement in one of his tubercle cases in 10 minutes; this, I think, shows that there is a large working range. I also agree with him that even a small quantity of tubercle emulsion decomplements to some degree normal serum, which is shown when equal quantities of normal serum and tubercle emulsion are mixed together. But when heated serum is also employed this decomplementing is to some extent masked, owing no doubt to the increased quantity of sheep's amboceptor present, intensifying the activity of the complement. Also, whereas the loss of complement in 5 c.mm. may be so great as to fail to produce hæmolysis, this is not the case with 10 c.mm. I find that the complement present in 2½ c.mm. is the minimal which will produce a trace of hæmolysis. Hence, if half the complement in 5 c.mm. of normal serum is deflected there will be no hæmolysis, but if half is removed from 10 c.mm. there will be hæmolysis. Dr. Emery does not state the quantity of serum he employs. The anti-complementary substances in serum appear to be removed by heating; Nagouchi also mentions this point in connexion with the syphilis test. I always read a trace of hæmolysis as a negative result, if the salt tube has only faintly hæmolysed. I also agree with Dr. Emery that an old emulsion gives poor results; this I think is due to the growth of a short broad bacillus.

So as to simplify the technique, I have employed during the last week an emulsion of tubercle bacilli in 5 per cent. carbolic and 1 per cent. salt. This I have standardised with normal and tuberculous sera. I think that this emulsion will keep active for some weeks. Dr. Emery records his results by the length of time required to deflect the complement, and he obtains the extremely interesting result that this can occur in 2½ minutes.

On Dec. 21st, 1910, and again later experimenting with my own serum and a few other normals, ten minutes from drawing the blood, I found the following. 1. That from 2½ to 3 c.mm. were required to show some hæmolysis, this being complete with 5 c.mm. (0·5 c.mm. of sheep's corpuscles). 2. That when the serum was incubated with 20 parts 0·75 per cent. salt for one hour at 98° F., and then the sheep's corpuscles added, there was no trace of hæmolysis with 6 c.mm. of serum, from 7 to 9 c.mm. being necessary to produce a faint tinge (incubated for one hour with the sheep's red cells). That is to say, fresh serum loses a considerable degree of hæmolysing power when warmed to 98° F. for one hour. 3. That when the serum has stood for one hour over the clot the hæmolysing substances appear to gain stability and not to lose by warming to 98° F. Hence, the age of the serum is an important detail, serum from three to six hours old being the best, for though some complement is lost there is a marked gain in stability. By diluting human blood with 9 volumes of 1·5 per cent. salt clotting is prevented, and some of this plasma (equal to 10 c.mm. of pure plasma) diluted with 20 parts of 1 per cent. salt and mixed with sheep's corpuscles produced no hæmolysis.

From these experiments (though too few in number) I infer that the quantity of complement in circulating blood is much less than that in serum, and that clot gives to the serum some substances (complement or amboceptor) which increase its hæmolytic activity for sheep's corpuscles. Dr. Emery states that with normal serum in the presence of tubercle emulsion complement is absorbed in 15 to 25 minutes when warmed in the incubator. He does not mention the quantity of serum employed, but if 5 c.mm. I can quite understand if the serum is fresh that this loss will occur with 1 per cent. salt also. I find that a temperature of 125° F. decomplements serum in 10 minutes. In view of these latter results I now leave the serum and tubercle emulsion at room temperature (60° F.) for one and a half hours before adding the sheep's corpuscles; and, when preparing the decomplemented serum, employ a temperature of 125° F. for 10 minutes, as a greater temperature and time may damage the immune bodies.

As regards the immunity index, I have only put this forward tentatively, suggesting it as some indication of

progress, for I have found immune bodies to increase with improving health, and to be quite absent (as judged by hæmolysis) in one case during a negative phase. On the other hand, the immune bodies appear to decrease as the disease subsides. Dr. Emery appears to agree, on the whole, that immune bodies are favourable. As regards the opsonic index, I found a few days ago three cases (two tubercle of lung and one of spine) with indices below 0·7 to possess the highest immunity index and a high degree of complement. (I have found the reverse also.) 10 c.mm. of serum (three hours old) was mixed with 10 c.mm. of tubercle emulsion (carbolised) and left for half an hour at room temperature (60° F.). That the complement was deflected I was able to show also by the serum losing two-thirds of its activating power on washed human leucocytes (15 minutes at 98° F.). This was demonstrated by adding staphylococci. Employing syphilitic serum and antigen of heart muscle a far greater reduction was obtained. This is simply employing Sir Almroth Wright's observation that leucocytes require complement. I hope later to suggest this method as a means of diagnosing syphilis on the line of Hecht's modification, but also employing heated with unheated serum.

In view of these and other experiments on the same lines, I venture to think that a low opsonic index is frequently due to the presence of a high degree of tuberculous antibodies. These deflect the complement in the presence of the tubercle emulsion employed in the opsonic test. By the same hæmolytic experiments I have shown fixation of complement in two cases of gonorrhœal joint and one of staphylococcal. This will explain, I think, the marked specificity of the opsonic index and its limitation for diagnostic purposes, as complement is frequently greatly in excess to the immune bodies present. An abnormally high opsonic index means, I think, an excess of complement and absence of immune bodies, though probably Dr. Emery's suggestion of the presence of a new substance which inhibits the antigen-immune combination is more correct. Both methods appear to show conclusively that antibodies are produced in tubercle.

A patient suffering from tubercle or other inflammatory disease must constantly be losing complement through intravascular deviation, as tubercle bacilli have frequently been found in circulating blood, but the sera of such patients, as far as my experience goes, show an excess of hæmolysing power for sheep's red cells (excess of complement). An excessive dose of tuberculin would probably reduce the complement in the circulating blood, and in this way be harmful. A falling opsonic index would at once show this, and indicate danger.

When gauging by hæmolytic experiments the progress of a patient undergoing therapeutic inoculation one should, I think, endeavour to estimate not only the degree of immunity but also the degree of complement. This is shown by the tubes C and D in the method I described in THE LANCET of Dec. 31st, 1910. (The diagnosis is made by comparing tubes A and D.) And, as complement is absorbed by all toxin-immune compounds, all other organisms complicating a tuberculous lesion require attention. By using 40 c.mm. of heated with 10 c.mm. of unheated serum I find (in my present limited experience) that it is clearly possible to distinguish between the normal and the slightly tuberculous, and thus give after two or three examinations a definite diagnosis.

I am, Sir, yours faithfully,

Jan. 7th, 1911. V. B. NESFIELD.

## DIET AND INOPERABLE CANCER.

*To the Editor of* THE LANCET.

SIR,—May I be permitted to ask your readers to send to my hospitals a sufficient number of cases of inoperable cancer in order that the effects of medical treatment may be tested? I have for years believed that wrong food was an important factor in the etiology of cancer, but only recently have I seen cases that gave the impression that by alteration of diet we may sometimes cure. I might easily take up columns in arguing the *pros* and *cons* of the cases that have given me this impression, but my object is to put the matter to the test of further experience. In order that this may be done, I want cases in which there is a probability of at least six months of life, as change of diet produces little visible effect on the body under three months, but I may say that even in cases where treatment comes too late to cure it appears to mitigate very decidedly the pain and suffering of death from malignant disease.

Shortly, the treatment consists in putting the patient as quickly as possible under one form of uric-acid-free diet and from that on to one of nuts and fruit chiefly, the only fluid besides fruit juice being distilled water. I have been trying to get such cases for more than 12 months, but they are quite difficult to obtain, for cases of this kind are generally sent back to their friends or to homes for the dying, as hopeless; hence this letter. The names and addresses of males may be sent to the senior house physician at the Metropolitan Hospital, and those of females to the senior resident at the Royal Waterloo Hospital.

I will undertake to publish the result in all cases I am able to accept for treatment. I think that 30 to 40 cases so treated would answer the question whether cure of real cancer by such means is possible. Hitherto it has been assumed, when such cases recover, that the diagnosis has been wrong. I doubt whether this assumption is always correct.

I am, Sir, yours faithfully,

Brook-street, W., Jan. 5th, 1911. ALEXANDER HAIG.

## REBATE ON PETROL TAX FOR MEDICAL MEN.

*To the Editor of* THE LANCET.

SIR,—The letter of your correspondent in THE LANCET of Jan. 7th, p. 58, on the difficulty experienced by medical men in obtaining the rebate of 3*d.* per gallon on petrol consumed before Dec. 31st, 1909, is borne out by my experience. On April 5th, 1910, I supplied the Excise officer at Stratford, London, E., with properly certificated receipts for all the petrol used by me in 1909, and a declaration and application for repayment of duty, the whole of which documents were to his personal satisfaction. Hearing nothing further I wrote on Nov. 26th, 1910, asking for an explanation as to non-receipt of the sum claimed, and on Nov. 29th I received this reply:—

Customs and Excise, Deanery-road, Stratford, E.,
29th Nov., 1910.

SIR,—In reply to your letter of the 26th instant, I beg to inform you that Mr. Harris, for the Cripps Cycle and Motor Coy., 24-28, Woodford-road, Forest Gate, after repeated personal enquiries and correspondence, has failed to produce evidence to substantiate the certificates given on the three invoices that the full duty has been paid to the Crown on the motor spirit supplied to you. I have therefore to return your application, together with the invoices in question.

I am, Sir, your obedient servant,
THOS. SAUNDERS, Officer of Customs and Excise.

Dr. J. S. McDonagh, 235, Romford-road, Forest Gate, E.

Like your correspondent, I have been too disgusted with my failure to recover rebate for 1909 to make further futile applications, which would probably only result in some other ingenious loophole to avoid payment.

I am, Sir, yours faithfully,

Forest Gate, Jan. 8th, 1911. JAS. S. MACDONAGH.

*To the Editor of* THE LANCET.

SIR,—"Medical Motorist" appears to have been particularly unfortunate. I obtained the 3*d.* per gallon rebate on the petrol bought between April and Dec. 4th, 1909, through the firm which supplied me, and this without any formality. I called at the local Customs office a week ago and was given two forms to fill up, one for the petrol bought during the remainder of December, 1909, and one for that bought during 1910. I had to obtain from my petrol dealers details of the amount of petrol supplied, with a signed certificate to the effect that a total of so many gallons had been sold to me and that the full duty thereon had been paid to the Crown. I sent the forms and this certificate to the local office, and to-day received a cheque from the head office for the amount claimed, except that for some reason or other only 1½*d.* a gallon was allowed on petrol supplied on Dec. 30th, 1909, whilst 3*d.* was allowed on that supplied on Dec. 11th.

I am, Sir, yours faithfully,

Guildford, Jan. 7th, 1911. R. W. C. PIERCE.

## INVALIDITY INSURANCE.

*To the Editor of* THE LANCET.

SIR,—The letters from Mr. John J. Scanlan and Mr. Noel A. Humphreys which appear in THE LANCET of Dec. 17th are important contributions to a very important subject. I admit at once that the statistics to which I personally have access are based on the experience of business and professional men. Moreover, the figures quoted in mine of Nov. 25th have reference to the experience of the

"Century" office during the last 25 years. It seems to me that the rate of sickness in the friendly societies is at least a guide to the tendency in the general rate of invalidity. That the rate of sickness experienced by friendly societies is increasing admits of no doubt. The following figures are of interest:—

| Ages. | Rate of sickness per member per annum in weeks. | | | | | |
|---|---|---|---|---|---|---|
| | Manchester Unity, 1846-48. | Manchester Unity, 1856-60. | Manchester Unity, 1866-70. | A.O.F., 1871-75. | Friendly societies, 1876-80. | Manchester Unity, 1893-97. |
| 20 to 24 | 0·68 | 0·83 | 0·75 | 0·82 | 0·85 | 0·90 |
| 25 ,, 29 | 0·76 | 0·82 | 0·81 | 0·85 | 0·87 | 0·95 |
| 30 ,, 34 | 0·84 | 0·86 | 0·93 | 0·97 | 1·02 | 1·06 |
| 35 ,, 39 | 0·94 | 1·00 | 1·06 | 1·15 | 1·24 | 1·27 |
| 40 ,, 44 | 1·18 | 1·24 | 1·26 | 1·37 | 1·47 | 1·58 |
| 45 ,, 49 | 1·51 | 1·55 | 1·64 | 1·71 | 1·89 | 1·99 |
| 50 ,, 54 | 2·03 | 2·01 | 2·22 | 2·27 | 2·39 | 2·75 |
| 55 ,, 59 | 3·21 | 3·02 | 3·05 | 3·21 | 3·36 | 4·02 |
| 60 ,, 64 | 5·06 | 4·64 | 4·72 | 4·59 | 5·17 | 6·31 |

I just add that a rough investigation of the "Century" experience points to the same conclusion—viz., that the rate of sickness is increasing. I do not ask that the fact that sickness payments are on the increase is "conclusive proof of a real increase of sickness." I do, however, hold that in the absence of population statistics the experience of the friendly societies, and incidentally of the "Century" Company may be held to at least point to the fact that the rate of sickness generally is on the increase.

I am, Sir, yours faithfully,

Edinburgh, Dec. 30th, 1910. W. A. ROBERTSON, Actuary.

# PATENT MEDICINE IN THE UNITED STATES AND IN CANADA.

(FROM A SPECIAL CORRESPONDENT.)

*Present Position in the United States.*

THE Food and Drugs Act of the United States has, since its passage in 1906, checked to a considerable extent the sale of many objectionable nostrums. Several States have passed laws tending in the same direction, and although in some States the sale of patent medicines is comparatively unrestricted, yet there is not the free and open sale of such products as was formerly the case. The laws in general prescribe the qualifications necessary for a pharmacist to engage in the practice of selling medicinal agents, regulate the sale of poisons and narcotics, and forbid the sale of adulterated and misbranded drug products. However, there is at present no Federal law which prohibits unregistered or unlicensed persons from sending into inter-State commerce such commodities, although they cannot be sold locally by them, nor indiscriminately even by registered or licensed pharmacists or medical men. The laws of the United States are by no means ideal as regards nostrums, but at least a beginning has been made; the Bureau of Chemistry of the Department of Agriculture has wielded vigorously the powers placed in it by the Food and Drugs Act, and numerous prosecutions have been made.

*Campaign against Certain Patent Medicines.*

The main effect brought about by the policy of the Bureau of Chemistry has been to educate the public to a sense of the harmfulness of many of the patent medicines. For instance, Dr. L. F. Kebler, chief of the Division of Drugs of the Bureau of Chemistry, published a short time ago a pamphlet pointing out the harmfulness of many of the habit-forming drugs which are contained in so many of the most widely advertised nostrums. He was especially insistent on the fact that the majority of the so-called soothing syrups for infants had in their composition narcotics of one kind or another, especially opium and its derivatives. These soothing syrups are extremely commonly used in America, and Dr. Kebler made out a list of the more prominent ones which contain habit-forming drugs. Of course, a great difficulty met with in America in the endeavour by the authorities to prove to the public that many nostrums are harmful to health is that the lay journals advertise them extensively. The same difficulty is doubtless met with in Great Britain. Wonderful to relate, during the summer of last year an influential daily paper in Philadelphia took the matter up, quoted Dr. Kebler as to the composition of several of the more notorious infant soothing syrups, and initiated a newspaper campaign against the use of these remedies. Further than this, the most conspicuous daily paper of Chicago followed suit and pursued a campaign against babies' soothing syrups with typical western energy. The writers of the articles did not mince words in describing the action of the manufacturers of such products, but vituperated all concerned in the traffic in strenuous western style. Cartoons, too, were brought into use to illustrate more graphically the effect of the syrups, and at the Food Exhibition held in Madison-square Gardens, New York, a few months ago, Dr. Kebler used one of these cartoons on a screen as a part of the Bureau of Chemistry's exhibit to educate the public regarding harmful nostrums generally. Newspapers in different portions of America have interested themselves in the matter to a greater or less extent, and thus the community is beginning to have an intelligent comprehension of the facts of the case.

Moreover, the United States Post Office Department is coöperating with the Division of Drugs. This division in 1909 made analyses of 15 medicinal agents represented as cures for various maladies and sent or prescribed through the post in violation of the postal laws. The investigations required not only the analysis of the samples of the medicines used in the treatments, but also a study of all the claims and representations made for treatment, that the Postmaster-General might be advised as to whether or not false and fraudulent representations and promises had been made. In 1909 and during the past year several successful prosecutions have been brought by the Post-Office Department against nostrum proprietors for violations of the postal laws.

It is impossible to over-estimate the educative influence of the various pamphlets sent out by the Division of Drugs, describing the composition and explaining the injurious nature of many of the well-known quack remedies. It is in this educative propaganda that the utility of the work being done by the Division of Drugs is mainly to be found. Some little time ago Dr. Kebler, Dr. Morgan, and Dr. Rupp, all connected with the Bureau of Chemistry, published a bulletin on the harmfulness of headache powders. These powders are very largely used in America, especially by women, and are no doubt also used on a wide scale in England. It was first shown that acetanilid, antipyrin, and phenacetin are very frequently made use of in the preparation of mixtures intended for the relief of headache and other minor aches and pains; it was likewise shown that the injudicious use of these drugs has produced bad effects in many instances; and furthermore that the number of reported cases of poisoning by at least one of them has increased notably during the past few years. A list was compiled of the authentic cases of poisoning by these drugs, and this plainly proved that headache powders sold indiscriminately are a distinct menace to the public health.

*Position in Canada.*

In Canada, as has been mentioned in THE LANCET,[1] an Act respecting proprietary or patent medicines was passed in July, 1908. Regarding its effectiveness opinions are divided. The general view appears to be that in parts it is not clearly enough expressed and that it is not strictly enforced. The sale of patent medicines is large; most of them are made in the country on account of the large import duty, and many of the large nostrum manufacturing firms in the United States have branch manufactories in Canada. The patent medicine evil is present in Canada to an extent comparable to that in the United States; but whereas in the United States the Department of Agriculture, through the Bureau of Chemistry, is taking vigorous steps to abate it, in Canada the public has not as yet been fully aroused to the fact that the indiscriminate sale of patent medicines is a source of danger. If strictly enforced the Canadian Patent Medicine Act might, many

[1] THE LANCET, Dec. 19th, 1908, p. 1853.

persons believe, meet the exigencies of the situation, but this remains to be proved.

*Proposed Action in the United States.*

The volume of the patent medicine business in the United States is enormous. Three years ago it was worth about $75,000,000 (£15,000,000) a year. In the opinion of the officials of the Bureau of Chemistry the most dangerous nostrums are those which are termed habit-forming—that is, which contain alcohol or narcotics.

The action proposed by Dr. Kebler to counteract the endeavours of the nostrum manufacturers to foist their harmful wares upon a public generally ignorant of their injurious qualities is: 1. To educate the public by means of the press and by pamphlets and lectures. 2. To enact laws forbidding the sale of all injurious habit-forming drugs, such as cocaine, morphine, opium, heroin, &c., and their derivatives and preparations by retail, except on prescriptions of medical men. 3. To require a permanent record, subject to State and Federal inspection at all times, to be kept of all transactions in such drugs, whether wholesale, retail, or by means of prescriptions. 4. To enact laws forbidding the handling of any of these products except by manufacturers, wholesale and retail druggists, and others legally qualified. 5. That the State boards of health, or other governing bodies, should be empowered to withdraw the licences of medical men who prescribe or of druggists who sell these articles for other than legitimate purposes. 6. That a Federal law should be enacted forbidding the interchange in inter-state commerce of habit-forming drugs or of preparations containing them, except through the customary channels of trade, and then only when complete records of all transactions have been kept.

The hopeful feature of the situation as regards patent medicines in the United States and in Canada is that something is being done to restrict their sale. Of course, when the community at large understands the bearings of the case, laws to restrict the sale of objectionable quack remedies will quickly be called for and enforced. The fight will be hard as the patent medicine interests are very rich, and every device that money can command will be put into practice to avoid restrictive legislation. It is worthy of note that cocaine is regarded with especial disfavour in the United States. Stringent regulations as to the sale of the drug exist in practically all the States.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

*The Smoke Nuisance.*

AT the annual meeting of the city justices a long discussion took place on the smoke nuisance. Manchester suffers grievously from this infliction, which is more noticed by visitors than by residents, who have become habituated to it. It was suggested at the meeting by a speaker that the city justices were too lenient as to fines. In London and Leeds, one gentleman said (I do not know his authority for the statement), fines were doubled until they reached the maximum of £40. It appears that in 1899, which is certainly going back rather far, 178 cases were reported by the inspectors. Of these 47 were cautioned and 131 were summoned before the justices, who imposed a fine in 90 cases only, and the fines averaged less than 50*s.* each. In the majority of cases such a fine as 50*s.* would not be felt. In the end the resolution that the justices should consider the matter was rejected by 25 votes to 15. It seems a pity that the powers of darkness prevailed, for the constant presence of smoke is a material disadvantage to Manchester, both from a health and a business point of view. Living, as many of the city justices do, beyond the smoke zone, they hardly feel the mere nuisance so keenly as some who live in the centre of things, and their sympathies will be with the manufacturers.

*Hospital Sunday Fund.*

At the recent annual meeting of the Manchester and Salford Hospital Sunday Fund it was announced that during the year £4398 had been received, being an increase over the previous year of nearly £800. The sum distributed among the hospitals was £4100, as compared with last year's distribution of £3400. In his appeal for more help the Lord Mayor said that if the hospitals were municipalised an increase of 10*d.* in the £ on the rates of Manchester would be entailed, "besides losing for the hospitals that personal attention and sympathetic care which they now got from many people." The weak point about the voluntary system is, of course, that a comparatively few persons bear all the burden.

*Bequest for Royton Hospital.*

The late Mr. Kershaw, F.R.C.S. Edin., L.R.C.P. Edin., &c., former medical officer of health of Royton, left £50,000 in order to provide a hospital for the neighbourhood. Royton is a manufacturing town not very far from Oldham. The Royton council wishes to spend £10,000 or £15,000 on the building, and devote the remainder of the fund to endowment.

*Langho Inebriates' Home.*

The above institution came under discussion on Jan. 5th at the meeting of the city justices. Mr. E. J. Broadfield said that they wanted more information as to the cost and efficiency of the treatment at the Langho Home. He said it was admirably managed, but very costly, and asked if it were well to send women there who were quite hopeless. It is no doubt a serious problem to solve. Mr. T. Gregory said that those women who had 50 to 100 convictions against them must either go to prison or to Langho, where they were much better off than in prison. Those who went to Langho from Manchester had on an average 50 convictions against them. "It was impossible to cure such people, but at Langho they were kept at less expense, and more to their own advantage, than in prison." Mr. A. Porter said that in these cases there was only one remedy—to shut them up for life, and they should consider the possibility of providing institutions where such people could be kept for life. In the meantime, considerable extension has taken place in the accommodation at Langho for women drunkards, and the Home Department has certified that the reformatory is fitted for the reception and detention of 294 female inebriates, being an increase of 99 in the number of inmates authorised on Nov. 25th, 1905. As if to illustrate the uselessness of a three years' detention at Langho a case was brought before the Recorder, Mr. Tobin, K.C., M.P., at the Salford quarter sessions on Jan. 9th, four days after the discussion by the justices. A tall, masculine-looking woman, named Lyons, aged 52, pleaded guilty to stealing some clothing on Oct. 30th last. She had already been four times before the Recorder, and altogether there were 33 convictions against her, most of them for drunkenness. In May, 1907, she was sent to Langho for three years as a habitual drunkard. She was discharged early last year, and on May 21st was again before the court for stealing. The Recorder sentenced her to six months' hard labour.

*Mentally Defective Children.*

The necessity for the permanent care of children mentally defective is becoming more widely believed and acted on. On Jan. 4th the Oldham town council passed a resolution to the effect that such children "should be cared for by public authorities after they leave school." Councillor Hirst said that it had been found impossible to make mentally defective children in any sense self-reliant. They must be to some extent a burden on others and a danger to the community, and "they should be cared for in institutions provided by the public authorities and paid for by the legislature." But if all the chronic drunkards and all the defective children are to be practically segregated all their lives at the public expense, ratepayers will have a heavy burden.

*Kissing the Shuttle.*

In connexion with your recent note on this subject, a case reported by a sanitary inspector at Bacup is interesting. He visited a house where he found a case of phthisis, and ascertained that three persons who had worked on the same looms had all died from consumption. All had followed the universal practice of the weavers of threading the shuttles with the mouth.

Jan. 10th.

THREE lectures on the Comparative Anatomy of the Vertebrate Ear will be given by Mr. R. H. Burne at the Royal College of Surgeons of England, Lincoln's Inn-fields, on Thursdays, Jan. 19th and 26th and Feb. 2nd, at 5 P.M. The lectures are delivered in connexion with the University of London.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

*The University of Birmingham.*

THE Chancellor of the University, Mr. Chamberlain, has addressed an appeal to the city council through the Lord Mayor for a further grant to the University from the rates. The number of students has increased from 678, ten years ago, when an annual grant equivalent to a halfpenny rate was first made, to 957, and in the same period the professorial staff has risen from 29 to 37, while the junior staff has practically doubled. At present the income is far below the necessary expenditure. The increased Treasury grant of £50,000 to university colleges, promised by the Chancellor of the Exchequer, is to be apportioned on the basis of the local support afforded to each establishment, which forms an additional reason for further municipal assistance.

*Notification of Births at Erdington.*

The adoption of the Notification of Births Act at Erdington had formerly been opposed by the medical men of the district. The health committee of the urban council on the representations of the medical officer of health (Dr. A. Bostock Hill) has again given the question earnest consideration and now recommend that the Act be adopted. At the last monthly meeting of the Erdington district council the recommendation of the health committee was unanimously agreed to. The chairman stated that the medical men were now willing that the Act should be adopted, provided that the notification was by letter instead of by post-card, and that the county health inspector should not visit houses where properly qualified practitioners were in attendance. Dr. Hill said there could be no possible objection to the employment of letters as suggested. No difficulty had been experienced in Birmingham, Aston, Leamington, and other places where the Act had been adopted. The adoption of the Act in Erdington brings the district into line with the other suburbs included in the greater Birmingham scheme.

*Pathological Society of Great Britain and Ireland.*

This society held an interesting and well-attended meeting in the pathological department of the University on Jan. 6th and 7th. The members were entertained at luncheon in the University Club on Jan. 7th by the members of the staffs of the General and Queen's Hospitals, Mr. Jordan Lloyd, the president of the clinical board, occupying the chair.

Jan. 8th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*Vaccination in Scotland.*

THE working of the Vaccination (Scotland) Act, 1907, is giving rise to some concern. Previous to the passing of this Act Scotland was a well-vaccinated country, there was no provision for "conscientious objectors," and the number of parents declaring themselves such was small. The Act of 1907 provided a clause whereby vaccination might very easily be evaded. This clause consists of a declaration that in the opinion of the parent signing, vaccination would be injurious to the health of the particular child named. No objections to vaccination in general need be avowed, nor are parents required to undergo any examination before magistrates. The result, as might have been foreseen, is that the clause is being taken advantage of by the most ignorant of the people, sometimes on account of prejudices against vaccination, but often merely to escape the inconvenience of having an infant upset and fretful for a few days after the operation. The Registrar-General for Scotland in his report for the year 1908 estimates that in that year alone, as the effect, direct or indirect, of this Act, 20,000 unvaccinated children were added to the population of Scotland. The public health committee of the Edinburgh town council has had the matter under consideration for some weeks, and at a meeting of a subcommittee thereof on Jan. 7th it was proposed to memorialise Parliament to make an amendment on the 1907 Act with a view to reducing the numbers of persons at present taking advantage of the exemption clause. The Edinburgh Practitioners' Association is also moving in the matter. An application has been made to the public health committee by the National Antivaccination League, London, to be heard on the subject by deputation, and the subcommittee has arranged to hear representatives of the league.

*The University of Edinburgh.*

The annual report for 1910 shows the total number of matriculated students (including 624 women) to be 3366, of whom 1370 (including 21 women) were in the Faculty of Medicine. Of the students of medicine 615, or nearly 45 per cent., belonged to Scotland; 257, or nearly 19 per cent., were from England and Wales: 105 from Ireland; 96 from India; 245, or nearly 18 per cent., from British Colonies; and 52 from foreign countries, showing that the proportion of non-Scottish students of medicine is well maintained. Among the degrees conferred were: M.B., C.M., 1; M.B., Ch.B., 214; M.D., 76; and Ch.M., 2. The diploma in Tropical Medicine and Hygiene was conferred on five candidates. Of University Fellowships, scholarships, &c., the total annual value is £18,870, of which £3890 are in the Faculty of Medicine. A sum of over £5000 has been given to the University by Mr. Robert Munro, M.D. Edin., LL.D., of Elm Bank, Largs, Ayrshire, for the foundation and endowment of a lectureship in the University, to be known as "The Munro Lectureship on Anthropology and Prehistoric Archæology." Dr. Munro has himself been appointed first lecturer, and he is expected to deliver the first course of lectures during the academic session 1911–12. The Court has appointed Mr. A. Murray Drennan, M.B., lecturer on practical pathology. At the end of the summer session Dr. T. S. Clouston resigned the lectureship in mental diseases, which he had held since 1879, being its first incumbent. The report expresses its regret, and refers to his services in the advancement of science and in the improvement in the treatment of the insane. Mr. R. B. Thomson, M.B., is now second lecturer in anatomy, a vacancy having been occasioned by the resignation of Dr. David Waterston. Mr. David Wallace, M.B., C.M., Mr. J. M. Cotterill, M.B., C.M., and Mr. J. W. B. Hodsdon, M.B., C.M., have been appointed lecturers in clinical surgery. At the general Parliamentary election in January Sir Robert B. Finlay, M.D., LL.D., was elected, and in December he was re-elected (without a contest) Member of Parliament for the Universities of Edinburgh and St. Andrews. The Lords of the Treasury have intimated that they are prepared to make a substantial increase in the annual grant from the public funds to the University. Personal gifts are reported from Emeritus Professor Alexander Crum Brown, Dr. Henry Barnes of Carlisle, Mr. James Lyle, Emeritus Professor Campbell Fraser, and Mr. John Storer Bainbridge. A prize of £50—the twelfth Gunning prize—for Public Health has been instituted, and also an additional Hope Chemistry Prize of £30. A scheme of post-graduate courses in medicine, under the joint auspices of the University and the Royal Colleges of Physicians and Surgeons, is stated to have proved highly successful.

*Phthisical Paupers in Glasgow.*

The question of who is responsible for the care and treatment of phthisical cases amongst the poor and working classes seems likely soon to become acute in the city of Glasgow. The responsibility lies between the corporation and the parish council. Up to comparatively recently the corporation did not deal with the matter at all. Recently it has made notification of phthisis cases compulsory, and has established dispensaries in various parts of the city, and also at Bellefield it carries on the work of a small sanatorium where selected cases are taken in and treated. The notification is certainly a step in the right direction, but the arrangements for treatment originated by the corporation do not pretend to deal with all the phthisical cases of a large city. At present, therefore, a few of the cases more likely to recover are selected by the corporation for treatment in its sanatorium, whilst the serious and hopeless cases, involving longer residence in an institution and more expense, are left to be dealt with by the parish council. The parish council unfortunately is further hampered by restrictions which make it impossible for that body to deal with the problem in the only way which gives any hope of permanent success. It is compelled to take in the working man suffering from phthisis when he has become unfit for work in the advanced

stages of the disease, to give him medical care and maintenance during a protracted illness, and after his decease (for the mortality-rate is bound to be high in such cases) to support any dependents whom he leaves unprovided for. Should the parish council accept the responsibility of dealing with the disease, and demand that it should get the control of these cases in an early stage, then the Local Government Board steps in and forbids it to put on the rates men who, though afflicted with the incipient stage of the disease, are still able and willing to work and support their families. It seems only right that the parish council should be allowed to do as suggested, or, failing that, that the corporation, having adopted compulsory notification, should be compelled to carry out the logical sequence and to deal with those cases in isolation hospitals in the same way as it deals with scarlet fever and other infectious diseases. A report on the condition of Barnhill poorhouse recently issued by one of the medical inspectors of the Local Government Board seems likely to revive the whole question which for some time has been allowed to lie dormant. In Barnhill poorhouse, where most of the inmates are infirm and aged people, the medical inspector found 178 cases of phthisis requiring treatment in bed, and not isolated from the other inmates of the institution. The Local Government Board, on the strength of this report, has called upon the parish council to make more suitable provision for these patients. Naturally, under the circumstances, the parish council does not wish to spend more money on building in the present unsettled state of matters, and it urges that now is the time for the corporation to undertake the responsibility that really belongs to it in the matter.

*The Oldmill Poorhouse Medical Officership.*

The medical officership of the Oldmill poorhouse was frequently considered by the last parish council, but the salary offered for the duties of visiting medical officer was considered insufficient by the local branch of the British Medical Association, which body discountenanced acceptance of the post on the parish council's terms, and stipulated £150 as the minimum salary. A deadlock occurred, and the council remitted the matter to its successors for decision, an interim provisional appointment being made. At the meeting of the poorhouse committee of the new council on Dec. 27th last it was resolved by 5 votes to 4, after two hours' discussion, to offer £150 per annum, and to advertise for applicants. The medical man appointed will visit the institution, situated about 2½ miles from the centre of the city, every alternate day. It was also recommended that the council should offer £40 for a dispenser, the dispensing at present being done by the resident medical officer. An amendment was offered to appoint a resident male medical practitioner at a salary of £200 per annum, with board and residence. The recommendation will come up for consideration at the next council meeting.

Jan. 9th.

## IRELAND.

### (FROM OUR OWN CORRESPONDENTS.)

*Paupers and Pensions.*

WITH the removal of the pauper disqualification a large number of old people took their discharge on Jan. 6th from the various union workhouses throughout the country, and many others were struck off the lists for outdoor relief. In the North Dublin union 84 inmates took their discharge, and about 150 people in receipt of outdoor relief were struck off the lists. In South Dublin union 174 inmates left the house on pensions, and there are said to be still some 400 claims under investigation, while some 350 have gone off the outdoor relief lists. In the Dublin unions alone it is calculated that nearly £6000 a year will be saved to the ratepayers. In country unions the figures are smaller, though in the south particularly they remain considerable.

*Infantile Mortality in Dublin.*

A conference is to be held in the Mansion House, Dublin, on Jan. 19th, to discuss the best means of dealing with infant mortality in Dublin and of securing the advantages of the Early Notification of Births Act recently adopted by the Dublin corporation. The summons to the meeting is signed by the Lord Mayor, the medical superintendent officer of health, and the masters of the various maternity hospitals in Dublin. The chief object is to organise a band of voluntary workers, under the control of the public health department, to aid young mothers and their infants, as has been successfully done in Edinburgh, Glasgow, and elsewhere.

*Congress of the Royal Institute of Public Health.*

Arrangements are being pressed forward for the congress of the Royal Institute of Public Health in Dublin next August. The authorities of Trinity College have granted the use of their buildings for the congress. There will be 16 sections, the chief of which are chemistry, pathology, bacteriology, veterinary science, engineering, architecture, education, vital statistics, tuberculosis, and town planning.

*Zymotic Diseases in Dublin.*

Scarlet fever is so prevalent in Dublin that the Cork Street Fever Hospital is taxed to the utmost. Eighty beds out of its 200 are occupied with this disease, many cases being of a severe type. So great is the congestion that the managing committee has had to issue a special appeal for funds. Diphtheria and whooping-cough are also prevalent.

*Medical Man as High Sheriff.*

Mr. J. B. Story, F.R.C.S.Irel., has been appointed High Sheriff of County Tyrone. Mr. Story is a member of Council of the Royal College of Surgeons in Ireland and surgeon to the Royal Victoria Eye and Ear Hospital, Dublin.

*The Health of Belfast.*

At the meeting of the city council of Belfast held on Jan. 2nd, the medical officer of health submitted the accompanying table showing the number of cases of infectious diseases notified during 1910 (calculated on the number notified during the 50 weeks ended Dec. 17th, 1910), as compared with 1906–7–8–9 :—

| — | Typhus fever. | Typhoid fever. | Scarlet fever. | Simple continued fever. | Puerperal fever. | Small-pox. | Diphtheria. | Membranous croup. | Erysipelas. | Total. |
|---|---|---|---|---|---|---|---|---|---|---|
| 1910 ... | 7 | 97 | 719 | 16 | 14 | — | 232 | 5 | 260 | 1355 |
| 1909 ... | 6 | 90 | 355 | 39 | 23 | — | 195 | 10 | 260 | 978 |
| 1908 ... | 19 | 274 | 323 | 208 | 22 | — | 221 | 27 | 294 | 1388 |
| 1907 ... | — | 356 | 531 | 270 | 29 | 1 | 257 | 37 | 341 | 1892 |
| 1906 ... | 9 | 551 | 1193 | 366 | 17 | — | 233 | 40 | 340 | 2749 |

The table given below was included, showing the number of deaths and the average annual death-rate per 1000 of the population from all causes, and from zymotic diseases, typhoid fever, and phthisis during the year 1910, calculated as above, as compared with 1906–7–8–9 :—

| Year. | All causes. | | Zymotic diseases. | | Typhoid fever. | | Phthisis. | |
|---|---|---|---|---|---|---|---|---|
| | No. | Rate. | No. | Rate. | No. | Rate. | No. | Rate. |
| 1910 ... ... ... | 7343 | 18·7 | 1109 | 2·8 | 19 | 0·04 | 833 | 2·1 |
| 1909 ... ... ... | 7028 | 18·2 | 511 | 1·3 | 20 | 0·05 | 811 | 2·1 |
| 1908 ... ... ... | 7523 | 19·5 | 689 | 1·8 | 57 | 0·15 | 880 | 2·3 |
| 1907 ... ... ... | 7870 | 21·3 | 615 | 1·7 | 82 | 0·22 | 926 | 2·5 |
| 1906 ... ... ... | 7379 | 20·1 | 905 | 2·5 | 90 | 0·24 | 1015 | 2·7 |

The extremely low typhoid death-rate in 1910—that is 0·04—is gratifying, but the high zymotic death-rate—2·8—is unsatisfactory, as is also the death-rate from all causes—18·7 (18·2 in 1909); and the abnormal phthisis mortality—2·1—shows no fall from the previous year. During 1910 1109 deaths from zymotic disease gave a rate of 2·8, largely due to the epidemics of measles (which caused 522 deaths) and whooping-cough. The infantile mortality in 1910 (up to Dec. 17th) was 144, as compared with 135 in 1909, 147 in 1908, 135 in 1907, and 143 in 1906. The rate in 1910 is largely attributable to the number of deaths from measles, of which 522, equal to a rate of 1·3 per 1000 population, were registered—as high a rate as that from all zymotic diseases in 1909. It is clear the

epidemics of measles and whooping-cough in 1910 brought about the high general death-rate (18·7), and the very high infantile mortality (144). In speaking on the matter the chairman of the public health committee referred to measles and whooping-cough as being "two diseases over which the corporation had very little control"; but clearly, as custodians of the public health, the corporation will have to take far stronger measures than it has done in the past to deal with these maladies, so terrible in their effects. A reduction in their mortality can be effected only by managing them like other zymotics, as the dispensary medical officers of health suggested in their resolution forwarded to the public health committee during the measles epidemic—that is, by notification, disinfection, and isolation in hospital. The high phthisis mortality (2·1) was ascribed at the meeting to Belfast becoming the consumptive dumping-ground for the North of Ireland. The corporation has passed a resolution forbidding the admission of anyone into the Forster Green Sanatorium, where there are municipal beds, unless after a residence of one year in Belfast, and the public health authorities allege that the board of guardians admit consumptives into the Abbey Sanatorium without any such stipulation, so that patients outside the Belfast area enter that institution. At a meeting of the guardians on Jan. 3rd, however, this was denied, and in a report from the Abbey Sanatorium committee it was stated that, as far as the officials could ascertain, the patients admitted into their sanatorium did belong to Belfast. The chairman of the sanatorium committee said that the shortest period of residence in Belfast before admission to the sanatorium had been six months. What is wanted in this discussion is the facts. If the Belfast city public health authorities raise a barrier against admitting any person into their sanatorium unless after a residence of a year in the city, the country boards will be sure to send back to the city all cases which leave Belfast or the surrounding districts.

*David Taylor, M.D. Q.U.I.*

News has just reached Belfast of the death of a well-known Ulster man, Dr. David Taylor, which occurred in November at Kinchunpore Tea Estate, Cachar, Assam. Born at Greyabbey, Co. Down, in 1857, the deceased was educated at the Belfast New Academy, at Queen's College, Belfast, and at St. Thomas's Hospital, London. In 1877 he obtained the M.D. of the old Queen's University of Ireland, and he became a Member of the Royal College of Surgeons of England in 1879. Proceeding to India, he settled at Hailalsandi, adding to his *clientèle* the Chotla Bhéel, and soon acquiring an extensive practice. A skilful physician, a sportsman, and of pleasing social qualities, he became very popular. Some years ago, on returning to Ireland, his friends in India presented him with a yacht—the *Dolphin*—which was a familiar craft in the North of Ireland. Finding, however, that the climate of Ireland did not suit him, Dr. Taylor returned to India in 1909. He was in the North of Ireland last year and again raced the *Dolphin* in Belfast Lough and in the Clyde. Dr. Taylor was a man of the most kindly disposition, and his good qualities endeared him to all those who knew him.

Jan. 11th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Medical Diplomas Granted during the Academical Year 1909–10.*

IN the course of the academical year 1909–10 the French faculties of medicine granted 915 State diplomas and 52 university diplomas—i.e., a total of 967 diplomas of doctor of medicine. The period in question was moreover the first during which no diploma of *officier de santé* was granted. The number of diplomas given by some of the individual faculties was as follows: Paris, 450 State and 34 university diplomas; Algiers, 3 State diplomas; Bordeaux, 70 State and 3 university diplomas; Lyons, 109 State and 3 university diplomas; Montpellier, 120 State and 13 university diplomas; Nancy, 32 State and 2 university diplomas; Toulouse, 55 State diplomas; and Beyrout, 32 State diplomas.

*Osteomalacia of Tuberculous Origin.*

At a meeting of the Academy of Medicine held on Jan. 3rd M. Poncet and M. Leriche, speaking on the subject of osteomalacia, said that it was a disease of the bone marrow, and that it was due to a variety of causes acting in several different ways, but whatever its form or the date of its appearance might be, it consisted of a group of symptoms presenting some degree of clinical uniformity. Etiologically there were cases which might be said to be of ovarian, or suprarenal, or thyroid origin, according as the secretory functions of one or other of these three glands was insufficient or disordered, but such glandular lesions were only secondary causes of the disease, and it was important to know what were the primary causes of these pathological conditions. As a result of their personal observations M. Poncet and M. Leriche have proposed a new hypothesis—namely, that tuberculosis was often a primary cause of the disease. They considered that the infective action of the tuberculous virus was demonstrable both in essential diffuse osteomalacia and in partial osteomalacia. The latter form of the disease—i.e., the local manifestations which were so common in the tibia, in the femur, and in white swellings of the knee and the hip-joint, were not due either to general impairment of nutrition or to immobilisation, but were the result of tuberculous infection, which might be either latent or active and might affect either a neighbouring or a distant part.

*Notification of Infectious Diseases in Algeria.*

At the same meeting of the Academy of Medicine M. Vincent recommended that the list of diseases scheduled for compulsory notification should be enlarged by the addition of relapsing fever, Malta fever, trypanosomiasis and piroplasmosis in the human subject, and leprosy. In consequence of its great frequency, its severity, and the large amount of blindness which it caused in Algeria, he also recommended that granular ophthalmia should be added to the list. He said that children who had not received treatment or who were still in an infectious stage ought to be excluded from the schools. With regard to malaria, he spoke in favour of the observation of the endemic index—i.e., the determination of the percentage of children under 15 years of age whose blood contained the hæmatozoon, or, failing this examination, the determination of the percentage of children with enlargement of the spleen. Local inquiries ought also to be held with regard to the frequency of first attacks, the forms of the disease, and the preventive measures which had been taken or required to be taken, such as methods of dealing with the haunts and breeding-places of the anopheles, mechanical devices for protection against the insects, and other means to the same end. The public exhibition of placards in French and Arabic would be useful in spreading a knowledge of some elementary facts connected with malaria, such as the parts played respectively by mosquitoes, by former sufferers from the disease, and by children as carriers of germs.

Jan. 9th.

## ITALY.

(FROM OUR OWN CORRESPONDENT.)

*The Organisation of the Italian Schools of Obstetrics.*

THE new regulations concerning the creation and organisation of the schools of obstetrics for the education of qualified midwives in Italy have now received the Royal sanction. It is now required that a midwife, to obtain the necessary qualification, shall have to undergo a course of practical as well as theoretical instruction at one of the above-named schools, to be created in every town in which there already exists a medico-surgical faculty or an institute for gynæcology and obstetrics, and also in the towns of Aquila, Bari, Catanzaro, Milan, Novara, Venice, and Vercelli. The schools in the latter towns will be under the direction of the universities in their neighbourhood; Naples in the case of the first three, Turin for Novara and Vercelli, and Padua for Venice. Every school will be under the direction of a professor, at least one assistant holding a qualification in medicine and surgery, and a mistress-midwife (*levatrice maestra*). The schools must be connected with a maternity hospital or any hospital containing at least 15 beds reserved for maternity

cases and in which the total births during a year do not fall below 120 cases. The number of students is limited to three times the number of available beds. To obtain the qualification of midwife the candidates must be at least 18 and not over 36 years of age, in good health, and not disabled by any deformity likely to interfere with their work. A certificate of elementary education or the matriculation qualification is required, as well as a statement regarding good conduct. Candidates must also have been vaccinated, and in the case of unmarried women the consent of the father or of a guardian must be produced. The course of training lasts two years, and is divided into a theoretical and practical part; the first lasts one year and consists in lectures given by the director of the school. Practical instruction begins simultaneously with the theoretical course, and this knowledge is acquired at the bedside. Candidates will have to pass two examinations to obtain their qualification; the first will take place at the end of the first year, i.e., at the end of the theoretical course, and the second at the close of the second year. The first examination is to consist of a reply in writing to two questions, four hours being allowed (the paper must be written without any help) and an oral examination lasting half an hour. In the practical examination the candidate will have to send in a paper dealing with two cases treated by her under the guidance of the director or of his assistant; in addition there will be an oral examination lasting at least one hour, and dealing particularly with the report of the two cases sent in and also with the principal obstetric manipulations to be performed on the child, diagnosis of pregnancy, exploration, assistance at birth, the dangers and the precautions to be observed in the case of complications, and the duties of midwives in the exercise of their calling. The following scale of fees for candidates has been established:—

| | | |
|---|---|---|
| Matriculation tax ... | 12*s.* | |
| Inscription tax ... | 32*s.* | for the course of two years. |
| Examination fee ... | 19*s.* 2*d.* | |
| Tax of diploma ... | 8*s.* | |

The examination fee will be divided in equal parts among the examiners. There are at present about 14,000 women practising as midwives in Italy.

Jan. 7th.

# Obituary.

## EDWARD HOWARD COLLENS, M.B. LOND., L.R.C.P. LOND., M.R.C.S. ENG.

THE medical profession of Herefordshire has sustained a severe loss through the death at Vienna on Dec. 18th, 1910, of Edward Howard Collens, a week after undergoing an operation for the removal of a pituitary tumour. He had been under the joint care of Professor v. Frankl-Hochwart, Professor v. Eiselsberg, and Dr. O. Hirsch, by whom the operation was performed. The actual cause of death was broncho-pneumonia. He was born in Stourport in 1872 and attended the medical school of Mason College, Birmingham. In 1898 he obtained the Membership of the Royal College of Surgeons of England and became a Licentiate of the Royal College of Physicians of London, taking his degree M.B. Lond. in 1899. He was house surgeon at Queen's Hospital, Birmingham, and in 1901 went to practise in Hereford, where he gained the esteem of his colleagues and the affectionate regard and confidence of his patients. He was on the staff of the Hereford Provident Dispensary and for several years was superintendent of the fever hospital and police surgeon. He took a great interest in police ambulance work aad trained the men under his charge with great success. He leaves a widow to mourn her loss.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Lindmann, President of the Medical Council of the Archduchy of Baden.—Dr. Hermann Kestner, district physician of Mülhausen in Alsace, a grandson of Charlotte Kestner, whose maiden name was Buff, and who was the original of Goethe's Lotte in his "Sorrows of Werther." Dr. Kestner had been in retirement three or four years. He was 86 years of age. His father was the seventh son of Charlotte Kestner.—Professor Sprengel, privy medical councillor of Brunswick.

# Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF ENGLAND.—At the First Professional Examination of the Conjoint Examining Board held on Jan. 3rd, 4th, 5th, and 6th the following candidates were approved in the undermentioned subjects:—

*Chemistry and Physics.*—Johannes Willem Bouwer, London Hospital; Arthur Bulleid, Guy's Hospital; David John Evans, Epsom College and St. Thomas's Hospital; Ilse Fischer (Miss), Leeds University; John Vaughan Griffith, Liverpool University; William Tudor Gwynne-Jones, London Hospital; William Llewellyn Aplin Harrison, St. Mary's Hospital; Vincent Coram James, Middlesex Hospital; William Baly Jepson and Noël Sigismund Koch, St. Bartholomew's Hospital; Charles William Lakin, Guy's Hospital; Henry Guy Ludolf, Leeds University; James McDonnell, London Hospital; William Hubert Milligan, St. Thomas's Hospital; Harold Dobson Pickles, Leeds University; David John Platts, King's College; Robert Mowat Reid, St. Bartholomew's Hospital; Khan Sahib, St. Thomas's Hospital; Bryan Montague Tuke, Middlesex Hospital; and José Victory, Costa Rica and Guy's Hospital.

*Chemistry.*—Kenneth Leslie Bates, Guy's Hospital; Reginald Naunton Bates, Liverpool University; John Behesnilian, Charing Cross Hospital; Percy Herbert Burton, London Hospital; Arthur Stanley Carter, Middlesex Hospital; Henry Judson Grimshaw, Liverpool University; Henry Barry Hyde, St. Thomas's Hospital; John Robert John, University College, Cardiff; Philip Savage, Guy's Hospital; Noel Archibald Scott, St. Bartholomew's Hospital; Arthur Dighton Stammers, London Hospital; David Page Thomas, St. Bartholomew's Hospital; John Aylmer Tippet, St. Thomas's Hospital; Jurin Totton, Guy's Hospital; Walter Aslatt Turner, Hartley University College, Southampton; and Henderson Whyte, London Hospital.

*Physics.*—John Andrew, South Western Polytechnic, Chelsea; Joseph Herbert Bayley, London Hospital; Alfred Allwright Brown, Birkbeck College; William Barnes Buer, Guy's Hospital; Edmund Sheppard Cuthbert, St. Bartholomew's Hospital; Herman Gerald Dresing, Guy's Hospital; John Fox-Russell, Middlesex Hospital; Colin Charles Gordon Gibson, Guy's Hospital; Kenneth James Menteith Graham, St. Mary's Hospital; Gustaf Hahr, Polytechnic Institute, Regent-street; Richard Annesley Holmes and Lancelot Horsley, Guy's Hospital; Ernest Gwyn Howell, University College, Cardiff; Alexander Joseph Vincent McDonnell, London Hospital; Warre Harriott Alexander Pratt, Guy's Hospital; and Roy Bingley Pullin and Harold Ernest Pierpoint Yorke, St. Bartholomew's Hospital.

*Biology.*—John Gordon Ackland, Royal Albert Memorial College, Exeter, and St. Bartholomew's Hospital; Percy William Lavers Andrew, Middlesex Hospital; Kenneth Leslie Bates, Guy's Hospital; Johannes Willem Bouwer, London Hospital; William Alexander Clements, Manchester University; Oliver Francis Conoley, London Hospital; Herbert Carr Duggan, Guy's Hospital; John Eric Evans, Liverpool University; Moustafa Fahmy, Cairo, and London Hospital; Ilse Fischer (Miss), Leeds University; James Douglas Fleck, St. Mary's Hospital; William Tudor Gwynne-Jones, London Hospital; Alfred Risdon Hacker, King's College; George Harris Haines, University College Hospital; Douglas Vernon Halstead, Guy's Hospital; Walter Owen Hughes, Liverpool University; Vincent Coram James, Middlesex Hospital; William Baly Jepson, St. Bartholomew's Hospital; Charles William Lakin, Guy's Hospital; Marie Gertrude Gwendoline Calvert Link (Miss), South Western Polytechnic Institute; Noel Heathcote Seton Maelzer and Lancelot Turtle Montgomery, Guy's Hospital; Henry Maurice Peacock, Birkbeck College; Roy Bingley Pullin, St. Bartholomew's Hospital; Bertram Pyman, University College, Cardiff; Norman Ward Rawlings, Manchester Unversity; Noel Archibald Scott, St. Bartholomew's Hospital; Mian Mohammad Shaffi, London Hospital; Walter Aslatt Turner, Hartley University College, Southampton; and Francis Bernard Yonge, Middlesex Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—At the Primary Examination, Parts I. and II., held on Jan. 2nd, 4th, and 5th, the following candidates passed in the subjects indicated:—

*Chemistry.*—C. A. Hepburn, Manchester.

*Materia Medica and Pharmacy.*—H. Cox, Birmingham, and R. Jones, Charing Cross Hospital.

*Anatomy.*—A Abdelal, Guy's Hospital; D. Blair, Glasgow; H. Dudley, University College Hospital; N. E. Farr and F. C. Godding, Guy's Hospital; G. B. Holroyd, London Hospital; R. Jones, Charing Cross Hospital; H. E. Rose, Cambridge; and A. H. Taymour, Guy's Hospital.

*Physiology.*—A. Abdelal, Guy's Hospital; H. Dudley, University College Hospital; F. C. Godding, Guy's Hospital; R. Jones, Charing Cross Hospital; and H. E. Rose, Cambridge.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill announce the impending publication of "A Manual of Gynæcology," by Dr. T. W Eden, obstetric physician to Charing Cross Hospital. The object of the book, which is a companion volume to the same author's "Manual of Midwifery," is to present a comprehensive account of the diseases of women from the standpoint of pathology and treatment. The same publishers will shortly issue a book by Dr. J. B. Hurry of Reading on the subject of "Vicious Circles in Disease."—"A Text-book of Gynæcological Surgery," by Dr. Comyns Berkeley and Mr. Victor Bonney, is

announced for publication by Messrs. Cassell and Co. at the end of January. It represents the surgical experiences the authors have gained at the Middlesex Hospital and the Chelsea Hospital for Women, and is illustrated with nearly 400 drawings from the pencil of Mr. Bonney.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE.—A course of eight lectures on the Physiological Significance of Amines, will be delivered by Dr. H. H. Dale in the Physiological Institute, on Fridays, at 4.30 P.M., commencing Jan. 20th. These lectures are open, without fee, to all internal students of the University of London, and to such other persons as are specially admitted.

PRESENTATION TO A MEDICAL PRACTITIONER.—In the Auckland, New Zealand, City Council Chamber on Nov. 10th last Mr. Robert Stopford, L.R.C.P. Irel., and his wife, who are leaving Auckland to take up their residence in Sydney, were presented with a handsome tea and coffee service, a claret jug, and a hot-water jug by Mr. Stopford's friends and patients. Mr. Stopford was also presented with an illuminated address and chiming clock.

DONATIONS AND BEQUESTS.—The late Mr. John Bradshaw of Cheltenham has bequeathed £1000 to the Lancaster Royal Infirmary to endow a "John Bradshaw bed," £500 to the Manchester Royal Infirmary, £200 to the Cheltenham General Hospital, and £100 to the Harrogate Infirmary.—The late Mrs. Elizabeth Baker of Castle Wivelliscombe, Somerset, has left £10,000 each to the Bristol General Hospital and the Hospital for Consumptives, Winsley, Wiltshire.—The residue of the estate of the late Mrs. Gulielma F. Moss, amounting to about £15,000, has been bequeathed by the testatrix to Bolingbroke Hospital.—Under the will of the late Miss H. L. Maw the Manchester Royal Infirmary and the Lincoln County Hospital will each receive £1000 for the endowment of memorial beds in perpetuity.—The late Mr. S. Staniforth bequeathed £1000 each to the Sheffield Royal Infirmary and the Sheffield Royal Hospital, £300 to the Jessop Hospital for Women, Sheffield, and £200 to the Sheffield Children's Hospital.—The late Mr. J. Kershaw, F.R.C.S. Edin., left by will £50,000 for the erection of a hospital at Royton, Lancashire.—Lady Meux has left by will £1000 free of legacy duty towards the endowment of the Cheshunt Cottage Hospital.

PUBLIC HEALTH ADMINISTRATION IN TREGARON RURAL DISTRICT.—One of the most satisfactory and gratifying features of the many meetings which have been held during the past few months in various parts of Wales in connexion with the scheme for combating consumption is the reiteration by different speakers of the great need for effecting improvements in the sanitary condition of rural districts. At one such meeting, held at Aberystwith on Dec. 19th last, it was pointed out that there was an appalling amount of ignorance on sanitary matters, and that sanitary authorities must be stimulated into taking action to remedy existing conditions by the force of public opinion. While the county of Cardigan, from its situation and other favourable circumstances, should be one of the healthiest districts in the country, it has a higher death-rate from consumption than any other county in England and Wales. If the remaining sanitary authorities in the county of Cardigan are as indifferent to their responsibilities as the Tregaron rural district council appear to be there is ample justification for the statements referred to. In a report presented to the Local Government Board in 1907 by Dr. E. P. Manby concerning that district it was stated that the inspector of nuisances was in receipt of a salary of 11*s.* 6*d.* weekly. The area of the rural district is 189 square miles, and it contains about 2000 houses. Latterly the inspector's salary has been increased to £50 per annum, and he has devoted three days a week to his duties. In a communication read at a meeting of the district council on Dec. 20th last the Local Government Board stated that the duties of the inspector of nuisances could not be performed satisfactorily if so short a period was devoted to them, having regard to the amount of travelling necessary, and suggested that an adequate salary should be paid for whole-time services. The members of the council expressed indignation at what one member described as the unreasonableness of the council being overridden by a number of clerks in London, and it was seriously suggested that the services of an inspector should be dispensed with altogether. If any doubt could exist of the necessity of sanitary officers in the Tregaron rural district that doubt would be dissipated by even a cursory perusal of Dr. Manby's report. It is there stated that internally the conditions of many of the cottages are often far from satisfactory—e.g., floors of bare earth, walls damp, and rooms insufficiently lighted and ventilated. Houses are built back to earth and have no through ventilation. Windows are of small size and many do not open. This want of ventilation, in its possible relation to the high death-rate from phthisis, has been frequently referred to by the medical officer of health, and the council, in Dr. Manby's opinion, had been neglectful of its duty in not endeavouring to secure in systematic manner the improved lighting and ventilating of dwellings in their district. Other conditions reported on adversely by Dr. Manby make it abundantly evident that there is plenty of work ready to the hand of an energetic sanitary officer if he only receives the support from the sanitary authorities to which he is entitled.

THE FIGURES OF STATE EDUCATION.—A White Paper (Parliamentary Paper No. 338) was issued during the week above Sir Robert Morant's signature, entitled "Return Showing the Number of Boys and Girls Respectively on the Admission Registers of Ordinary Public Elementary Schools in England and Wales on the 1st Day of October in the Years 1907 and 1908, Arranged According to their Years of Age under the Areas of Local Education Authorities for Elementary Education." The form is dated Nov. 25th, 1910. In England on Oct. 1st, 1908, there were 5,637,340 boys and girls included in the return, of whom 11,170 were in schools not maintained by the local education authorities under Section 15. Of this number 2,842,415 were boys and 2,794,925 were girls. In Wales on the same date there were a total of 441,798 children included, of whom 223,040 were boys and 218,758 were girls. The grand total of England and Wales for Oct. 1st, 1908, was therefore 6,079,138 elementary school scholars. In London there was a total of 740,262 such scholars, of whom 372,988 were boys and 367,274 were girls.

## BOOKS, ETC., RECEIVED.

BAILLIÈRE, J. B., ET FILS, Paris.

Consultations Médicales. Maladies de l'Appareil Digestif et de l'Appareil Respiratoire. Par H. Huchard, Membre de l'Académie de Médecine, Médecin de l'Hôpital Necker. Price Fr.12.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Creech St. Michael, in the county of Somerset.

# Births, Marriages, and Deaths.

## BIRTHS.

BARNES.—On Dec. 28th, 1910, at New-road, Chatham, the wife of Harold Abbott Barnes, M.B., B.A. Oxon., of a son.

DONALD.—On Dec. 27th, 1910, at Liskeard, Cornwall, the wife of John Donald, M.D., of a son.

HULBERT.—On Jan 3rd, at Muttra, U.P., India, the wife of Major J. G. Hulbert, I.M.S., of a son.

PEDLEY.—On Jan. 6th, at "Maples," Orpington, the wife of S. E. Pedley, M.R.C.S., L.R.C.P., L.D.S., of a daughter.

SALL.—On Jan. 4th, at Mount Zeehan, Canterbury, the wife of E. F. Sall, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

UPWARD.—On Jan. 3rd, at Edfu, Romford, the wife of Harold Upward, M.B., of a daughter.

## DEATHS.

APPS.—On Dec. 26th, 1910, at Nablus, Palestine, Harriett Amelia Rachel Apps, M.B., B.S., of the C.M.S. Hospital, aged 30 years.

BRICKWELL.—On Jan. 10th, at Chigwell, Essex, Henry Taylor Brickwell, M.R.C.S., L.S.A., aged 64 years.

CORNISH.—On Jan. 10th, 1911, Edward Cornish, M.R.C.S. Eng., L.R.C.P. Lond., of sarcoma, at Bayswater, aged 47. R.I.P.

DAVIES.—On Jan. 9th, at Nutcombe, Sketty, Glamorganshire, Ebenezer Davies, M.R.C.S., aged 81 years.

PITCAIRN-BOOKLESS.—On Jan. 4th, at Ormiston, Eastbourne, James Pitcairn-Bookless, M.D. Edin., in his 66th year.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## THE RUBAIYAT OF SMITH TERTIUS.

UNDER this heading the *Manchester Daily Sketch* published at Christmas time some very clever verses, the concluding stanzas of which we quote. The earlier part of the ballad states how Smith Tertius speculates on the risks attending Christmas cheer, of which he has haunting memories, but decides that—

..... The Doctor, not the Saint, shall be his guide
And teach him mix his merriment with sense.

This resolution is strengthened by the appearance of an annotation in THE LANCET on the hygienic merits of the usual Christmas menu, and Smith Tertius sings:—

Then lo! *The Lancet*, hot from off the Press,
Acquits his Christmas cheer of harmfulness:
Both Bird and Pudding are innocuous
Unless they be indulged in to Excess.

Is this some new thing in the way of Traps
Placed by a set of foxy doctor-chaps
To lure unwary ones within their reach?
He ponders long and hesitates. Perhaps.

Would it conduce to less internal Strife
If I decide to lead the Simple Life,
And sparingly upon digestive bread
I spread my Nutter with blood-guiltless Knife?

Perhaps. But then just think what arrogance it
Would be to doubt the dicta of *The Lancet*;
And so, whatever Eustace Miles may say,
To-morrow, anyhow, I mean to chance it.

## ENCEINTE.

*To the Editor of* THE LANCET.

SIR,—With reference to your note in THE LANCET of Dec. 31st, 1910, p. 1947, on the etymology of the word *enceinte* as applied to pregnancy, I have come across the following definition and quotation in Cassell's Encyclopædic Dictionary—viz., Cloister (O. Fr. *cloistre*; Fr. *cloître*, from Lat. *claustrum* = (1) an enclosure; (2) a cloister). The figurative meaning is given as "Any place in which one is shut up, specially the womb." The quotation is: "As he brak not Maries *cloister* whanne that she was maad with childe.—*Wycliffe*: Select Works, i., 318." This is quoted, I suppose, from the manuscripts of the renowned John Wycliffe (1324-1384), a catalogue of which, I learn, was printed at the Clarendon Press in 1865 by the Rev. W. W. Shirley, ecclesiastical historian. The use of the word "cloister" so long ago and the definition that *cloître* is "*enceinte (des maisons des chanoines)*" (Boiste) are significant facts, so that the French expression, "*Elle est enceinte*," could be translated into English to-day, if we had retained and shortened the old expression used by Wycliffe, as "She is cloistered." I think it is plain from this quotation that the womb was then regarded as an *enclosure*—that is, as an *enceinte* or *clôture*.

I am, Sir, yours faithfully,

London, Jan. 6th, 1911. BLANCUS.

## A MEDICAL JOURNAL IN ESPERANTO.

*Internacia Medicino* (Kötzschenbroda-Dresden, H. F. A. Thalwitzer, pp. 32, price 6s. annually) is the title of a medical journal published monthly as the official organ of the Tutmonda Esperanta Kuracista Asocio, which signifies the International Esperanto Physicians' Association. It is edited by Professor H. Dor of Lyons, with the assistance of 21 collaborators in various countries, and contains, besides four pages of official information concerning the aforesaid society, articles on a New Mode of Dressing Wounds, by Dr. v. Oettingen, of Wilmersdorf; an address delivered by *Privat-docent* Kabanov, of Moscow, at the memorial meeting for Professor Ostroumov, on the Biologic Method of Clinical Examination of the Sick; Visible Speech for Deaf-mutes, by Dr. Spillmann, of the U.S. Bureau of Agriculture; the Dental Clinic and Dental Surgeon, by Dr. Klein, director of the Dental Clinic at Ulm; Ehrlich-Hata "606"; Obituaries of Ernst v. Leyden and Henri Dunant; and some pages of abstracts from current medical literature. It does not seem difficult for one with the necessary medical knowledge and a very moderate linguistic smattering to gather the sense of whole paragraphs at first glance. As the journal is sent gratis to the members of the above-named society, which we are told numbered in its second year, at the beginning of 1910, upwards of 600 physicians of various nationalities, literally "from China to Peru," it is obvious that the new language must be not only maintaining its ground, but making progress. The writers do not seem to fear to undertake translation into it of highly technical matters, and if they are understandable without danger of misapprehension by Esperanto readers, it is certainly a testimony in favour of the language.

## MOUNTAIN SICKNESS ON A TRANS-ANDINE RAILWAY.

AN article published in the *Engineer* of Dec. 23rd, 1910, gives a variety of particulars relative to a railway which is now in course of construction from Arica on the Pacific Coast of Chile across the main range of the Andes to La Paz, the capital of Bolivia. The line will have a total length of 260 miles and the highest portion of it will have an altitude of 14,000 feet. There are already two trans-continental railways in South America and it has been found that Europeans as a general rule are so injuriously affected by the diminution of atmospheric pressure at such an altitude that in all probability they would not be able to do at it one-half of the work of which they would be capable on the coast. Experience has shown that the output per man, even at altitudes of only 6000 feet or 9000 feet, has been reduced by fully 20 per cent. A large proportion of foreigners who make their way to these high altitudes never completely overcome the disease of *siroche*, or mountain sickness, and a few suffer so much that they are compelled to return to the lower levels almost at once. In addition to *siroche* extraordinary fluctuations of temperature will have to be encountered, for it is asserted that at one point on the line—namely, the head-quarters at Mauri River—the temperature may pass from − 27° C. to + 24° C. (a difference of 90° F.) in 24 hours.

## THE FOUNDER OF "THE LANCET."

*To the Editor of* THE LANCET.

SIR,—IN THE LANCET of Dec. 17th, 1910, page 1809, there is a reference to the founder of THE LANCET extracted from "Memoirs of Life and Work" by Dr. Charles J. B. Williams, F.R.S. The personality of Thomas Wakley struck so many persons that allusions to him abound not only in biographies where he is mentioned by name, but in essays and novels where he is alluded to as "the Crowner." A passage in "Friends of Bohemia," by E. M. Whitty, runs as follows:—

"There's Mr. Crowner, a veritable London man, as well known and as much a part of the metropolis as Temple Bar, a famous man in London, and outside London unknown. For we have our parish heroes, just as little Peddlington has. Crowner has lately got up a Commission of Chemists, and has proved that all our tradesmen adulterate all their goods. That ought to suggest a revolution, ought it not? But it hasn't made much sensation; and Crowner hasn't been assaulted or poisoned. The fact is, we expect to be swindled in England."

The suggestion that Thomas Wakley was unknown outside London is quite wrong, as the journalism of the day shows.

Edward Michael Whitty, who wrote the novel from which this passage is taken, was a well-known journalist who lived in the first half of the nineteenth century and at one time was employed as a Parliamentary summary writer on the *Times*. He was also on the staff of the *Leader*, where his sketches of proceedings in Parliament, which were marked by great vigour and a considerable power of sarcasm, were probably the forerunners of the Parliamentary sketch to-day so familiar to us all. Some of his newspaper articles have been collected and published, with additions, in book form under the title of "The Governing Classes of Great Britain: Political Portraits," and the phrase "governing classes," though used by Carlyle in Cromwell's Letters and Speeches, has been identified with Whitty's book. "Friends of Bohemia, or Phases of London Life" owed its birth to a quarrel between Whitty and his old friends on the *Leader*, whom, I learn from the "National Dictionary of Biography," he here ridicules in pungent style. The day has gone by when the points of the satire can be recognised, and the whole humour of the book has altogether evaporated. In its time it had a vogue, while it represents, I have heard, extraordinary literary dexterity on the part of its author, for he is said to have written it in a fortnight.

I am, Sir, yours faithfully,

Wimpole-street, W., Jan. 2nd, 1911. BOOKWORM.

## DIRT AND DISEASE AMONG SAVAGES.

THE homely scrubbing housewife, so much despised in certain quarters to-day, has, when we seriously consider her place in civilisation, played an immense prophylactic part during the ages. To her pail, broom, clouts, and soap is greatly owing the fact that dirt diseases do not become endemic, especially in the poorer quarters of towns. Disease, indeed, may be said to increase in direct proportion to the neglect of rubbing and scrubbing. This becomes particularly apparent when we consider savages, among whom housewifery is either rudimentary or unknown. Thus, according to Captain Schmitter of the Medical Corps of the United States Army, who has recently published a report in the Smithsonian Miscellaneous Collections, the Indians of the Upper Yukon have, since the arrival of the white man on his way to the goldfields, undergone a great and evil change in the matter of personal hygiene. In the past, according to George Maltock who visited Alaska in 1885, "small-pox and diphtheria struck them in epidemics, but they either died or soon recovered." Their wandering life led them constantly to abandon infected localities as well, it must be confessed, as sick members of their tribes. Now, with the advent of the white man, the Indians are no longer nomadic, and the conditions prevalent have become appalling. Says our authority "The Indians never wash more than their face and hands, and ar

consequently exceedingly filthy. Pediculosis and tuberculosis are ever-present indications of their unclean habits." The mediæval town, the slums of which were crowded with windowless hovels, may be said to have originated, or at least intensified, tuberculosis in Europe. The cabins of these Indians of the Upper Yukon suggest the Middle Ages. They are "as offensive as their (the owners') persons. They have no methods of sanitation. Tuberculosis far outweighs all other ailments. On entering the village one notices everywhere evidence of tuberculosis in the forms of humpbacks, hip-disease, scrofula, consumptive cough. Very few natives can be given a complete physical examination without disclosing some evidence of tuberculosis. Tonsillitis, respiratory disease, digestive troubles, and myalgia are ever present. Diphtheria, according to hearsay, kills off many in occasional epidemics." Yet these savages crowd to the hospital and are devoted amateurs of the out-patient department. They are bad patients, for they object to physical examination, though fond of medicine. In this they do not differ from their Western congeners. The medicine-man, who is also a magician, is their mainstay. He sings to drive away disease. It is suggested that a Government Commission should be appointed to teach them the simpler rules of hygiene, but savage custom dies hard, and these Indians are a doomed race.

## ALLEGED FORGERY BY A MEDICAL MAN.

Arthur Harrison, aged 47 years, once a medical student and described as a physician and surgeon, of Trinity-square, Borough, has been charged with uttering a cheque forged in the name of Dr. I. Burney Yeo. The prisoner made an explanation in which he referred to a letter received by him from Dr. Burney Yeo, from which he conceived and put in practice the idea of obtaining a cheque-book and forging cheques on Dr. Yeo's account. The truth of this matter is that Dr. Yeo, in response to a letter from the prisoner, who claimed to be an old King's College Hospital man, then in St. Bartholomew's Hospital as a patient partially paralysed, and asking for a subscription to a translation of Mosso's "La Paura," sent him a cheque for £1 as a subscription for four copies, and received a letter of profuse thanks also from the hospital. The prisoner admitted forging the cheque and also five others. Two cheques respectively for £60 and £10, both purporting to be signed by Dr. Yeo, were found on him when he was arrested. There were previous convictions against him and he was found guilty at the Central Criminal Court.

## BOVRIL PICTURES.

WE have received from Bovril, Limited, a framed artist's proof of their latest bonus picture, entitled "Blind Man's Buff," by Mr. Arthur J. Elsley, which is an excellent reproduction of an original oil painting exhibited in the Royal Academy in 1910. The full size of the gravure is 24×20 inches and of the paper 37×32 inches. We have also received two other reproductions of pictures (unframed) entitled "Tales of the Deep," by Mr. Joseph Clark (exhibited in the Royal Academy, 1910), and "Babes in the Wood," by Mr. Fred Morgan. Messrs. C. W. Faulkner and Co., Limited, London, are to be congratulated upon the excellence of the reproductions.

## POSOLOGICAL HINTS.

THE Fellows Company of New York, the proprietors of Fellows' compound syrup of hypophosphites, has issued a very useful compilation under the title of "Some Posological Hints and other Useful Information." The pamphlet opens with a section on the absorption and elimination of various drugs used in everyday practice, followed by a table of incompatibles. Next is given a broad classification of drugs (diuretics, cathartics, anthelmintics, and so forth), and finally a trustworthy table giving the overdose symptoms of drugs. Space is found also for recording the names of the authorities from whom the printed statements are taken.

## THE "PHILIPSON" SANATORIUM FOR CHILDREN.

THE medical report, by Dr. T. M. Allison, of this institution, situated at Stannington, Northumberland, shows that the health of the children generally has been good during the year ending Oct. 31st, 1910. Much attention is paid to defective teeth. Through the generosity of Sir W. H. Stephenson, Lord Mayor of Newcastle, a new wing for cases of localised tuberculosis is being built. Much care has been devoted to consumptive cases, with, on the whole, gratifying results.

*R.G.*—Certainly not; the spirit of the regulations is opposed to it.

*Lex.*—We cannot trace any legal decision bearing on the matter.

*G. S. F. W.*—The condition is unknown to medical science.

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

## A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1911:—

Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.
March 2nd–6th (Berlin).—Thirty-second Balneological Congress.
" 23rd (Paris).—First Congress of French Medical Journalists.
April (Berlin).—German Surgical Congress. (Thirty-ninth Annual Meeting.)
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
April 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.
" 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
" 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.
May 30th (The Hague).—International Congress on Opium.
May–October (Dresden).—International Hygiene Exhibition.
May–October (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May–October (?) (London, Shepherd's Bush).—Coronation Exhibition.
June (Paris).—First Congress of the International Medical Association for the Prevention of War.
" (Los Angeles, Cal.).—American Medical Association.
June 5th–8th (Kolberg, Prussia).—Fifth International Congress of Thalassotherapy.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
July 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
August 15th–21st (Dublin).—Royal Institute of Public Health.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September (Brussels).—Exhibition of Fractures.
" (Turin).—International Congress of Pathology.
" (Genoa).—International Exhibition of Marine Hygiene.
Sept. 11th–15th (Berlin).—National Congress for the Study and Prevention of Infantile Mortality (*Gouttes de Lait*).
" 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
" 18th–23rd (Sydney).—Australasian Medical Congress.
" 18th–24th (Turin).—Fourth National Congress of Hygiene.
" 24th–30th (Rome).—International Congress on Tuberculosis.
" 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.
October (Cologne).—International Congress of Criminal Anthropology.
Oct. 1st–4th (Liége).—Second Congress of Alimentation.
Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
(Date not fixed) (Montreal).—Canadian Medical Association.
(Date not fixed) (Rome).—International Exhibition of Social Hygiene.
(Date uncertain) (Turin).—International Exhibition of Industry and Labour.

In 1912:—

Spring (London).—Second Optical Convention.
July (?) (Cologne).—International Congress of Nurses.
September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
" Visit of German Medical Men to America.
Nov. 22nd–29th (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

In 1913:—

(London).—Seventeenth International Congress of Medicine.
(London).—Historical Medical Exhibition. (Organised by Mr. Henry S. Wellcome.)
(Dresden (?)).—International Conference on Cancer.
(Washington).—Congress of American Physicians and Surgeons.
August (Buffalo).—Fourth International Congress of School Hygiene.

In 1914:—

(Vienna).—Third International Congress for Professional Diseases.

In 1915:—

(London).—International Prison Congress.
(London).—Imperial Exhibition (?)

THE following journals, magazines, &c., have been received:—*Journal of Inebriety, Guy's Hospital Gazette, National Health, Medical and Surgical Papers of the Massachusetts General Hospital (October, 1910), Rivista Ospedaliera, Official Gazette of the United States Patent Office, Auckland Weekly News, Pioneer Mail, Finchley Press, Bulletin de la Société Royale des Sciences Médicales et Naturelles de Bruxelles, Medical Bulletin of the University of Pennsylvania, St. George's Hospital Review, St. Bartholomew's Hospital Journal, Canadian Journal of Medicine, Journal of the Royal Institute of Public Health, Maryland Medical Journal, Berliner Klinische Wochenschrift, Clinical Journal, Gazette Hebdomadaire des Sciences Médicales, La Belgique Médicale, Times of India, Army and Navy Gazette, Broad Arrow.*

## METEOROLOGICAL READINGS.

*(Taken daily at 8.30 a.m. by Steward's Instruments.)*

THE LANCET Office, Jan. 11th, 1911.

# Medical Diary for the ensuing Week.

## SOCIETIES.

**ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).**

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—H. Charles Cameron, H. H. Dale): at 4.30 P.M.

Dr. Clive Riviere: The Rôle of Auto-inoculation in Medicine: a Plea for its Rational Extension.

Dr. A. P. Beddard: Some Points in the Treatment of Pneumonia.

PATHOLOGICAL SECTION (Hon. Secretaries—C. Bolton, J. C. G. Ledingham): at 8.30 P.M.

Dr. J. P. Candler: The Incidence of Gallstones and of Primary Carcinoma of the Gall Bladder and Biliary Passages in the Insane.

Mr. H. Seidelin: Demonstration of Certain Protozoan-like Bodies in the Blood Organs of Yellow Fever Cases.

Dr. H. R. Dean: Studies in Complement-fixation with the Typhoid and Paratyphoid Group.

Dr. W. J. Penfold: Variability in the Gas-producing Power of Intestinal Bacteria.

Mr. S. G. Shattock: Microscopic Structure of Uric Acid Calculi.

WEDNESDAY.

SURGICAL SECTION (Hon. Secretaries—Jonathan Hutchinson, L. A. Dunn): at 5.30 P.M.

*Adjourned Debate:*

On the Operative Treatment of Cancer of the Rectum. The following gentlemen will take part:—Mr. A. Boyce Barrow, Mr. F. C. Wallis, Mr. P. Furnivall, and Mr. Lockhart Mummery.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—H. G. Adamson, J. H. Sequeira), at 11, Chandos-street, W.: at 5 P.M.

Exhibition of Cases.

NEUROLOGICAL SECTION (Hon. Secretaries—E. Farquhar Buzzard, Wilfred Harris): at 8.30 P.M.

Dr. F. E. Batten: The Progressive Spinal Muscular Atrophies of Infants and Young Children (Illustrated on the epidiascope by photographs and microscopical sections).

FRIDAY.

OTOLOGICAL SECTION (Hon. Secretaries—H. J. Marriage, Sydney Scott), at 11, Chandos-street, W.: at 5 P.M.

*Cases and Specimens*

Will be shown by Dr. W. Milligan, Mr. Arthur Cheatle and Mr. G. J. Jenkins, Dr. G. C. Cathcart, and Mr. Chichele Nourse.

*Paper:*

Mr. C. Ernest West: The Bacteriology of Chronic Post-nasal Catarrh: a Preliminary Study of Fifty Cases.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—Reginald Morton, G. Harrison Orton): at 8.30 P.M.

Mr. J. Hall-Edwards: The Treatment of Cancer by X Rays and Radium (followed by a Discussion to be opened by Dr. Frank Fowler).

---

ROYAL METEOROLOGICAL SOCIETY, Institution of Civil Engineers, Great George-street, Westminster, S.W.

WEDNESDAY.—7.30 P.M., Ordinary Meeting. 7.45 P.M., Annual General Meeting. Report of the Council for 1910. Election of the Council for 1911. Mr. H. Mellish (President): The Present Position of British Climatology.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—8 P.M., Prof. J. A. Thomson (President): Annual Address.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Adjourned Discussion on Sir Rubert Boyce's paper on Yellow Fever in West Africa.

---

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.**

MONDAY.—4 P.M., Dr. T. C. Fox: Clinique (Skin). 5.15 P.M., Lecture:—Dr. T. Thompson: Anæsthesia as an Aid in Diagnosis

TUESDAY.—4 P.M., Dr. G. N. Pitt: Clinique (Medical). 5.15 P.M., Lecture:—Dr. N. Raw (Liverpool): Modern Methods of Treatment of Tuberculosis.

WEDNESDAY.—4 P.M., Mr. T. P. Legg: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. A. McNab: Myopia.

THURSDAY.—4 P.M., Mr. A. Carless: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. J. Clarke: Treatment of Certain Common Fractures.

FRIDAY.—4 P.M., Mr. R. E. Bickerton: Clinique (Eye).

**POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.**

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Armour: Drainage in Abdominal Surgery.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Davis: Throat and Ear Diseases (Clinical Lecture I.).

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine (Lecture I.).

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Davis: Throat and Ear Diseases (Clinical Lecture II.).

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Saunders: Clinical (with cases).

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

**LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.**

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 2.15 P.M., Special Lecture: Mr. Turner: Operative Wounds and Injuries.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 4.30 P.M., Special Lecture:—Dr. Lister: Bronchial Affections in Children.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4.30 P.M., Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.**

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. E. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient: (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture:—Mr. E. Gillespie: Talipes and its Treatment.

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.**

TUESDAY AND FRIDAY.—3.30 P.M., Clinical Demonstration:—Dr. J. Taylor.

**HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.**

TUESDAY.—5.15 P.M., Demonstration:—Mr. H. A. T. Fairbank: Deformities—Genu Valgum; Genu Varum; Curved Tibiæ; Flat-Foot. (Special Post-Graduate Course.)

THURSDAY.—4 P.M., Lecture:—Dr. Thursfield: Purpura.

FRIDAY.—5.15 P.M., Demonstration:—Mr. H. A. T. Fairbank: Deformities—Congenital Talipes. (Special Post-Graduate Course.)

**ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.**

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Acne Vulgaris in its Three Stages—I., Comedo; II., Indurata; III., Necrotica.

**ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.**

TUESDAY.—3 P.M., Prof. F. W. Mott: Heredity. (Lecture I.).

FRIDAY.—9 P.M., Prof. Sir James Dewar: Chemical and Physical Change at Low Temperatures.

**ANCOATS HOSPITAL, Manchester.**

THURSDAY.—4.15 P.M., Dr. E. B. Leech: Visceroptosis. (Post-Graduate Clinic.)

---

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY (16th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

**TUESDAY (17th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

**WEDNESDAY (18th).**—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

**THURSDAY (19th).**—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

**FRIDAY (20th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor. 9 A.M., Major, 2 P.M.).

**SATURDAY (21st).**—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1910 were given in THE LANCET of Dec. 31st, 1910.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 1 0 | One Year ... ... ... | £1 5 0 |
| Six Months ... ... ... | 0 12 6 | Six Months ... ... ... | 0 14 0 |
| Three Months ... ... | 0 6 6 | Three Months ... ... | 0 7 0 |

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

### TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

## Communications, Letters, &c., have been received from—

A.—Mr. J. Astier, Asnières; A. B.; Mr. T. Allen, Box; Dr. Amorim, Rio Man; Aerators, Ltd., Lond.; American Society of Tropical Medicine, Watkins, Secretary of; Dr. J. J. Abraham, Lond.; Dr. T. M. Allison, Newcastle-on-Tyne.

B.—Mr. F. A. Brockhaus, Lond.; Messrs. W. H. and R. J. Bryce, Colinsburgh; Mr. H. A. Barker, Lond.; *Brain*, Lond., Editor of; Messrs. C. Birchall, Liverpool; Dr. W. B. Brownlie, Lond.; Dr. A. H. Brehaut, Guernsey; Messrs. Boulton and Paul, Norwich; Mr. E. Bougault, Paris; Bedford County Hospital, Secretary of; Mr. A. Banks, Lewes; Messrs. P. Blakiston Sons and Co., Philadelphia, U.S.A.; Mr. R. G. Brown, Glasgow; Mr. Hugh Bayly, Lond.; Mr. A. Benthall, Lond.; Lieutenant N. Bapty, Victoria, British Columbia; Mr. W. Bryce, Edinburgh; Mr. N. Basak, Drug, India.

C.—Dr. J. S. Chater, Lincoln; Mr. R. J. Coulter, Newport; Dr. J. L. Chundra, Calcutta; Messrs. J. and A. Churchill, Lond.; Mr. Arthur H. Cheatle, Lond.; Dr. G. A. Crowley, Sutton-on-Sea; Dr. R. A. Caldwell, Bournemouth; Clark's Syphon Stove Co., Lond.; Miss Chesbro, Willoughby, U.S.A.; C. R.; Cheltenham General Hospital, Secretary of; G. W. Carnrick Co., New York; Messrs. A. Constable and Co., Lond.; Messrs. S. Clark and Co., Lond.; Mr. R. Charles, Lynn; Dr. G. Herbert Clark, Glasgow; Colliery Guardian Co., Lond.

D.—Mr. J. Dowling, Tipperary; Derby Corporation, Medical Officer of Health of; Miss Caroline Redford Daly, Lond.; Dudley Dispensary, Secretary of; Denver Chemical Manufacturing Co., Lond.; Messrs. Davis and Co., Lond.

E.—Messrs. Elliott, Son, and Boyton, Lond.; Mr. R. Evans, Pwllheli.

F.—Messrs. Fannin and Co., Dublin; Right Hon. Robert Farquharson, Finzean; Forward Publicity Co., Birmingham; Fermanagh County Hospital, Enniskillen, Secretary of; Messrs. W. B. Fordham and Son, Lond.; Mr. J. Nesbeld Forsyth, Lond.; Dr. Elizabeth T. Fraser, Tollokshields.

# A Lecture
ON
# SOME POINTS IN THE DIAGNOSIS OF ORBITAL DISEASE.

*Delivered at the London School of Ophthalmic Surgery on Oct. 21st, 1910,*

BY J. STROUD HOSFORD, F.R.C.S. EDIN.,
ASSISTANT SURGEON, ROYAL EYE HOSPITAL, LONDON; ASSISTANT OPHTHALMIC SURGEON, LONDON TEMPERANCE HOSPITAL.

LADIES AND GENTLEMEN,—He who would accurately interpret the phenomena of disease or become an expounder of Nature's secrets must have something more in him than the mere capacity for taking pains; he should have something more than the mere clinical instinct; he should have an accurate memory of his past cases, combined with an intimate knowledge of the structure and functions of the parts concerned. In studying orbital disease from the clinical standpoint you will find that an intimate knowledge of the anatomy of the orbit and its adjacent structures is essential, whilst a groundwork of the embryology and ethnology of the face and skull will greatly aid you in a certain class of cases. But important as it is to cultivate these knowledges, yet it is just as important to cultivate what I call the clinical faculty, by which I mean the mental note-taking and continual mental comparison of one case with another of the same class. Written notes are of the greatest value, but for a diagnostician mental notes are more so, because they are ready to hand on the spot. The diagnosis of deeply seated orbital disease is often so very difficult that no knowledge of a set of symptoms is sufficient for the purpose, and you will find mental notes of similar cases you have seen and treated before of far more value to you than all the books you may read upon the subject.

Throughout the universe I apprehend that life is nowhere exactly the same; no sarcoma is exactly similar to its fellow in the same class; and so it is necessary for us to remember that we ought not to expect pathological processes in Nature to present the same picture, although they be similar and due to identical causes. Just as we know that the human race is continually altering, so we know that the presentation of disease to us is also. There is but little doubt that the severest forms of syphilis, as seen in the clinical departments to-day, are yet not the same, either in their severity or their sites of attack, as they were, say one hundred years ago. From the perusal of the writings of the surgeons of earlier years of the nineteenth century upon orbital cases, one is disposed to think that syphilitic swellings were vastly commoner then than they are now, for from one's own observations syphilitic caries and necrosis of the orbit is exceedingly rare, if we exclude the margin. Even the great Mackenzie, whose unrivalled experience was obtained when syphilis was rampant in Europe and notoriously badly treated—even he admits of only having seen one undoubted case of necrosis of the orbit from specific disease. Nowadays the sites for it are the neighbourhood of the lacrymal bone and the rim of the orbit, and even here I have never seen an exfoliation, but only gummatous thickening with a suppurating focus and perhaps bare bone. So that we may say that it is quite rare for the orbit to be attacked by syphilis in the form of gumma or necrosis, especially if we compare it with the cranium and its contents and the sphenoidal cavernous sinuses, where gummata are not very rare. It is, however, quite probable that all the hyperostoses of progressive nature and certain of the exostoses have been syphilitic in origin, for they are undoubtedly affected by large doses of iodide, sarsaparilla, and by mercurial inunction.

## DIAGNOSIS.

For diagnosis methodical examination of your patient is very important, and in examining the orbit and head in general do not forget the habits of body and general constitution of your patient. In examining the orbit itself, when you have chronic cases of progressive proptosis to deal with and there is not much trouble with the lids, the following observations should be carefully made. The symmetry or asymmetry of the two sides of the face and orbits Quite a number of patients have not only a slight difference in level of the two orbits, but the eyes on the two sides are not the same distance from the mid-nasal line, and one may be more sunken in the orbit than the other. These points are important in measuring your patient for spectacles. The state of the skin and feel of the lids and rim of the orbit should be noted; the interpupillary distance, the mobility and proptosis of the eyeball; the site of headache, pain, and tenderness; is there pain if the eyeball is pressed very slowly and gently backwards? is there fluctuation? the state of the inner canthus and caruncle and lacrymal apparatus; and, lastly, do not forget to tap with your finger in the neighbourhood of the orbit, as you may elicit a valuable symptom thereby. In all chronic and very obscure cases it would be wise to get the opinion of the nasal surgeon upon the nose and accessory sinuses and antri, but you should systematically look yourself for pus beneath the middle or superior turbinated bones. If there is any there is almost certainly ethmoidal disease; if there is none it does not exclude it.

Now a line drawn vertically through the orbit, dividing it into an inner and outer half, will place two-thirds of orbital disease upon the inner side and one-third upon the outer, and disease is far commoner of the left than of the right orbit. But pus which has slowly more or less invaded the orbit from one side and become chronic and encapsuled may present itself as a tumour on the extreme opposite side, and leave the site from which it sprang, to all appearances, quite natural. I recently had a beautiful example of this in the wards of this hospital. The patient was a woman, who came to the hospital with a circumscribed, fixed, firm, smooth, painless swelling at the upper and outer margin of the right orbit, about as large as a walnut, apparently attached to the bone. The whole of the orbital contents were elsewhere normal. I dissected it out, and just as I had nearly finished I found it to be a collection of pus in a densely thickened capsule connected by a long, but very narrow, sinus-like tract, with the frontal sinus which was distended with pus and greatly diseased. The patient did well. In quite a number of these frontal sinus cases the first sign is a tumour presenting at the upper and inner angle of the orbit, or even bulging the whole of the inner wall. A larger percentage of disease and swellings of the inner half of the orbit is due to acute or chronic collections in the ethmoid, frontal, and sphenoidal sinuses, and to caries and necrosis of the lamina papyracea. A sarcoma or exostosis occurring within these is comparatively rare, but I here show you the photographs of another patient with enormous broadening of the face from a sarcoma in that region upon whom I operated in the hospital six weeks ago. The interpupillary distance was 75 mm., and yet mobility of the eyes was excellent and diplopia only present in the later stages of the malady, but each fundus showed papillitis.[1]

But these ethmoidal and sphenoidal diseases do not always present themselves to us as cases of orbital disease *per se*, such as cellulitis, abscess, necrosis, caries, tumour, &c. They quite as frequently cause more concealed trouble, and insidious trouble because it is concealed. For instance, there is one sphenoidal cell that is larger than the rest, and it is in direct contact with the optic nerve, since it forms part of the wall of the canal through which it runs. Some collections in the ethmoido-sphenoid suppuration expand this and press upon the canal and cause retro-bulbar nerve trouble, which ends in optic atrophy. It is my desire to try to diagnose this form of acute or chronic retro-bulbar neuritis early, as the patient may be saved from certain blindness thereby.

Now of recent years quite a number of observations have been taken upon the blind spot of Marriotte, and I here show you a roughly made board I had made three years ago upon which fairly accurate measurements of the normal and the diseased blind spot can be obtained. The blind spot can be measured in various diseases of the optic nerve, and always gives very reliable information as to the expansion of the nerve or its head. You will find that the diagram is generally vertically oval, slightly at first, and more so the longer the duration of the disease; and then if a central scotoma should form, as is not uncommon, the two blind spots are sometimes bridged across by a kind of dumb-bell connexion. Later still, a large universal scotoma may

[1] The patient has now (Jan. 16th, 1911) an interpupillary distance of 88 mm. and much broadening of the face and head.

precede total blindness unless something is done to relieve the patient. One more instance of the disastrous effects of chronic purulent conditions of the sinus and teeth and toxic absorption from them may be mentioned in the serous choroiditis, serous cyclitis, and sometimes chronic retro-bulbar atrophy which result from long-standing neglected diseases in these situations. Hardly a week passes in this hospital but that we could see one or other of the above diseases caused by oral sepsis or nasal and sinus disease.

More than half of the cases of orbital cellulitis arise from disease spreading from the inner wall of the orbit, which in the living subject is as thin as notepaper.

### ORBITAL CELLULITIS.

Let us consider, then, acute orbital cellular inflammation. The patient has general symptoms of malaise and fever, with drowsiness and marked irritability of temper in adults, which needs to be taken into account in treating the patient. There is acute, throbbing pain, tenderness, much swelling of the lids, with brawny œdema in some cases and marked engorgement of the veins in others, which may pass beyond the region of the lids to the forehead, temple, or cheek. The lids are generally separated by chemosed tissue, if severe, although the ptosis and capacity for great stretching of the upper lid covers the cornea. The proptosis is not merely of the eyeball, but in most cases of all the orbital contents, and is generally downwards, outwards, and forwards, because the commonest cause is trouble at the upper and inner angle of the orbit. It is displaced up and in, in maxillary inflammation. The chemosis is clear and gelatinous, there is no discharge, but the edges of the lids may be a little gummy. The eyeball, as a whole, is normal, the cornea clear and bright, the pupil natural and reacting to light; but mobility of the eye may be entirely abolished, and is always limited. The fundus is normal in the early stages, and for a long while, except in pyæmic and metastatic cases, when papillitis is common. If tension is not soon relieved by nature or by art the eyeball may be strangulated and mortify or be perforated, which is exceedingly rare, and then the parts shrink up or the septic process may spread backwards and start a fatal meningitis or septic sinus thrombosis; but it generally subsides under appropriate care and leaves a useful eye, with perhaps a little ectropion or entropion, if the eyeball is not affected. I have never seen a permanently paralysed muscle follow an orbital cellulitis, except ptosis, but optic atrophy frequently supervenes some months later. An abscess of the orbit points through the upper lid.

Orbital cellulitis should be early and freely treated by incisions, and careful search should be made for the pus, which is generally to the inner side of the median line and above; but be careful of injury to the levator palpebræ and causing permanent ptosis; be careful of injuring your pulley or its muscle; be careful of injury to your ciliary ganglion or optic nerve—nature hardly ever injures it, it is the surgeon; and lastly, be careful not to injure the veins, thus setting up septic phlebitis. It is safer, unless pus is actually pointing, to make your exploratory incision from the outer side.

Inflammation of the cellular tissue of the orbit may be due to blood states and metastatic inflammation. It is commonest in children and the aged, but it is far more usually due, at all ages, to trauma and spreading inflammation from contiguous cavities, especially the nasal and accessory sinuses of the skull, the antrum of Highmore from disease of the bones *per se*, from oral sepsis, especially Riggs's disease, or due to erysipelas or to carbuncle.

With regard to trauma it is surprising how trivial an injury will sometimes start a virulent orbital cellulitis; the opening of a Meibomian cyst has caused it, and it has frequently followed excision of the eyeball when there has been a conjunctival discharge, or panophthalmitis, at the time of the excision, which has terminated fatally.

It has been my experience to find that patients with orbital disease give histories of their trouble which can generally be relied upon. In other diseases of the body patients are not always to be believed; but I would suggest to you that in no other region of the body will you find the history of more aid to you than it will be in diagnosing orbital disease, and in doing so I would say that in my experience it is safe to rely on one's patient for an accurate account of the events and their sequence. They are far more reliable in giving details about orbital disease than they are in those of maladies of the eyeball. In spreading inflammations in particular the patient has given very definite and valuable localising aid in all the cases I have notes of. He has aided me in forming a conclusion as to where the process started and as to its mode of spread in all of my cases but one. Let me give you two instances of orbital cellulitis spreading from ethmoidal sinus disease. They had both been long under the nasal surgeons. In one the man stated definitely that he had felt something go on to the inner side of the eyeball whilst blowing his nose, and the eye got painful an hour later; and on making an incision on the fourth day I found the lamina papyracea eroded and a hole in it, and pus and mucoid secretion came away. In the other case there was the usual history of nasal trouble and aching at the root of the nose and between the eyes, but no history of the patient having felt anything give way. In this latter case there was pus in large quantity along the inner wall, but no bare bone or bone pain, and I believe the process was not due to direct extension by expansion, but probably along the perforating vessels. It is important to get your patient to try to find which way he can move his eyeball with the least pain. At first he will tell you that he cannot move it, especially as he cannot open it. Sometimes this is true, and then you lose a valuable aid to diagnosis. But more often, although intensely swollen and exquisitely tender, especially if you make him rotate the good eye well to one or other side, he will say that there is more pain when he moves it, or attempts to move it, in a certain direction. The direction of the pain is generally the direction of the lesion, and is not so valuable when the trouble is deeply seated about the apex. The septic processes which spread from the antrum and perforate the orbital plate of the superior maxillary bone are less successfully treated than the nasal side cases because of the extensive necrosis and prolonged suppuration, the absence of the natural drainage to be got from ethmoidal cases, and from the great tendency to meningitis and sinus thrombosis. They want thorough and energetic treatment more than any other spreading inflammatory cases I know of. They may occur in quite young babies, for we had one in the hospital this summer. Here are a few notes of it:—

The patient was a female child, aged 6 weeks, who had been well for the first five weeks of life. The mother stated that six days before bringing the child to the hospital there was a discharge from the roof of the mouth, the left nostril, and the left upper alveolus. Two days later the left eye became swollen and prominent, and the child cried continually. The case was admitted to the hospital by the house surgeon, and when I saw the patient there was marked orbital cellulitis, swelling and œdema of the lid, and the eyeball was dislocated upwards and inwards. There was considerable chemosis, and apparently fluctuation of the lower and external part of the orbit. The pupil was dilated, but it reacted to light. The cornea, and apparently the fundus, were normal. The right eye was normal. The left ala nasi was pushed down and flattened by the orbital cellulitis and maxillary swelling. There was pus from the left nostril and from the left upper alveolus, of a greenish, thin nature. Under chloroform an incision was made at the outer portion of the protruding inner surface of the lower lid, and about an ounce of fœtid bone pus escaped. Dead bone could be felt downwards and backwards under the eyeball, showing the whole of the orbital surface of the superior maxillary bone to have been perforated and absorbed by pus which was probably from the antrum. Next day the swelling subsided considerably and the cornea was clear, but two days afterwards the swelling returned, and the right eyelid became very swollen and the eyeball considerably proptosed. Twelve hours later the patient showed all the signs of meningitis, which increased until she died two days later. In all the patient was in the hospital eight days. The post-mortem examination was made, and besides slight basal suppurative meningitis there was bilateral thrombosis of the cavernous sinus on either side, and the circular sinus and ophthalmic veins contained septic matter, the lateral sinus containing fluid and dark blood. The tissues in both orbits were infiltrated with pus.

The above is the youngest case on record of bilateral thrombosis of the cavernous sinuses, and, like all other cases of septic thrombosis of these sinuses on record, it terminated fatally, for, as far as I know, not a single patient in history with this disease has ever survived. The case is also o

paramount importance, since it shows how a trivial septic process in a baby's mouth may cause a serious and a fatal meningitis through the means of septic absorption from the oral cavity.

The orbital cellulitis sometimes set up by tuberculous bone disease is never a very tense one, nor does it cause the brawny swelling of the lids that is found in idiopathic and septic cases, whilst the eyeball is not fixed and can generally be moved by the patient, and there is far less pain and tenderness, and probably no febrile state. But not always, for I have notes of a case of a child who had quite high fever all the while—about four to six weeks—until the pus was evacuated and the necrosed bone removed, yet the orbital cellulitis was never very tense, the eyeball, although greatly proptosed and chemosed, could be moved; and there was no tenderness except on separation of the lids, whilst of course some patients get a temperature from merely nervous excitement.

### DIFFERENTIAL DIAGNOSIS.

Of the troubles that cause difficulty in diagnosing whether we have true orbital cellulitis at all, acute purulent conjunctivitis, acute thrombosis of the cavernous sinus, and acute lacrymo-adenitis, of these the second, cavernous sinus thrombosis, is most likely to cause great difficulty where there is no present, but only past, external ear disease. I have twice known the patient to be operated upon for orbital cellulitis when the cases have been those of sinus thrombosis. Here the diagnosis should not be difficult if we take a larger view of the patient and do not confine ourselves to the swollen orbital contents.

In the first place, sinus thrombosis is very sudden in onset, not very painful, if at all, in early stages; œdema of the forehead and over and about the mastoid is nearly always present, and in one of these cases tapping the mastoid elicited pain and tenderness. Secondly, the chemotic tissue protrudes between the lids more than usual, and the skin of the lids is soft and supple. Thirdly, since the veins are blocked, and the only possible means of draining the eyeball is through the communication of the angular with the facial and through the spheno-maxillary fissure with the tributaries of the internal maxillary, one expects to find some symptoms altering or abolishing vision, as well as ophthalmoscopic signs, if the upper lid can be sufficiently elevated. Engorgement of the retina and blindness should always be searched for in orbital cases. I have never known them in orbital cellulitis, except in the last stages, when fibrotic changes take place, but I have seen hæmorrhages and œdema of the retina in all my cases of cavernous sinus thrombosis and temporary reduction in vision, as well as permanent blindness in some of them. One case of non-septic thrombosis has always been vividly fixed upon my mind, and I will give you a short note of it.

The patient was an elderly gentleman, with malignant disease of the larynx, for which he was being treated by Sir Felix Semon. The patient suddenly had pain and swelling of the left orbital contents with great proptosis and chemosis, and only slight œdema of the lids, but by slowly and gently separating them the pupil, which was dilated, could be seen to react to light slightly. His vision was 6/36 and J. 14, with glasses. There were hæmorrhage and œdema of the retina. He had œdema over the mastoid and of the forehead on that side, very well marked. The diagnosis made by me was thrombosis of the cavernous sinus. In a few days' time the sight gradually came back, and on the eighth day was 6/9 and J. 1. Collateral circulation was sufficient to restore the retinal circulation, whilst the proptosis and swelling gradually abated. The patient died from the cancer of the larynx six weeks later. Non-septic monolateral cases of thrombosis of the cavernous sinus very frequently recover. I have notes of 14 cases, in all of which the patients got quite well.

The diagnosis of orbital cellulitis is often made in cases of blennorrhagia of the lacrymal sac and gonorrhœal conjunctivitis, but the history, the presence of a purulent discharge, combined with the absence of proptosis of the eyeball, should be sufficient for diagnostic purposes. The swelling and brawniness of the lids and the chemosis may be extreme, but you will on careful inspection find the eyeball sunken at the bottom of the chemosed tissue or normally placed—never displaced either forward or laterally or upwards, as it always is in orbital cellulitis. One notices, however, that in gonorrhœal ophthalmia of the severer types the eyeball is sometimes displaced a little down owing to the pus collections in the conjunctival folds above and to the thicker base of the upper lid. I have seen a child who was a mass of scrofulous disease of glands of the neck and several bones of the chest and the left scapula get dacryoadenitis, with intense swelling of the lids, which subsided in a week, leaving the gland chronically enlarged and palpable and riddled with pus. At first this case looked like one of cellular inflammation. I have seen acute œdema of the lids in children and young adults follow urticaria, and in both cases they had provisionally been diagnosed as orbital cellulitis. I have known retro- as well as intra-orbital hæmorrhage, with severe proptosis and chemosis, following blows, coughing, and scurvy-rickets, to be diagnosed as orbital cellulitis because of the proptosis, chemosis, and swelling. But the absence of inflammatory symptoms, of tumefaction of the lids, and of fever, with perhaps, but not always, the presence of effused blood into the lids or conjunctiva, ought to lead to a correct diagnosis; but here, as in all orbital disease, history is everything, for trauma, vascular hypertension as in coughing, or blood states, as in scurvy, would come to one's aid if necessary. Actinomycosis has once occurred in the orbit as a chronic abscess and caused difficulty; whilst in cases of anthrax, malignant pustule, and small-pox, although they may affect the orbit, yet I have never seen them. Not infrequently babies or children are brought to us with undoubted orbital cellulitis and no assignable cause can be discovered. You are aware that the sense of fluctuation in orbital disease is very deceptive, yet you make an incison and probe deeply, and in spite of your certainty of fluctuation you find no pus. You foment and purge and the inflammation passes off without a drop of pus ever showing itself. The same kind of cellulitis occasionally comes in adults who have been run down by an exhausting illness, such as influenza, and again no pus is found, and it gets well. The probability is that some of these cases originate from simple thrombosis of the ophthalmic veins with resulting œdema of all the orbital tissues. I exclude those cases where pus does not come at the time of the operation but follows next day or two, for these are cases where we have only failed to strike the pus and it has subsequently burst into the track of your incision. It is this class of cases in young children which is prone to follow that disease which every mother looks upon as nothing, and which is yet a scourge in the world in a variety of ways and undermines the vitality of the organism and is the starting point of so much infantile tuberculosis—I mean measles. If preventive medicine could do away with measles I believe it would prevent one-tenth of children's eye diseases.

Before I leave orbital cellulitis there is a condition which, although not actually orbital cellulitis, yet is so intimately related to it that when you see it for the first time you are sure to diagnose "orbital cellulitis"—and that is metastatic panophthalmitis. You are all acquainted with panophthalmitis which follows the ingress of virulent septic organisms by trauma, especially that form following cataract extraction in certain diabetic patients with perforating ulcers, for these diabetic patients have special proclivities and predispositions for sepsis. There is a certain amount of cellular inflammation, though not of all the orbital tissues as a rule. But when metastatic panophthalmitis arises you have no injury to help you, and at first you may be nonplussed.

Metastatic panophthalmitis was known to Tenon, Junker Himley, and others, who early recognised the danger of excision of the eyeball in these cases. They thought the condition one of milk metastasis, because it occurred so often in the puerperal state. Later, many cases were ascribed to other general pyæmic conditions, especially from bone disease, small-pox, cerebro-spinal meningitis, typhus and scarlet fevers. Roth and Herrnheisser have since very carefully studied the malady. The symptoms are much the same as those of traumatic panophthalmitis. It starts with pain, which is a continual throbbing, and the whole of the fifth nerve on that side aches. It is followed by rapid swelling, redness, and œdema of the lids, proptosis, chemosis, and exquisite tenderness of all the tissues, whilst the eyeball is fixed straight forward and cannot be moved. The diagnostic points are very important and are as follows. 1. The pupil loses its brilliant blackness and becomes dull grey or actually yellowish-green; there is a semi-dilated, immobile iris, with exudate on and in it, and a turbid aqueous

in a deep anterior chamber, because the septic process has spread from retino-choroiditis and irido-choroiditis to a general panophthalmitis. 2. The upper lid can generally be more easily manipulated. 3. Early and total loss of sight. 4. Glaucoma early supervenes with rupture sooner or later of the globe just outside the limbus with escape of purulent contents and subsequent shrinkage. Sometimes the course is more chronic and the case ends in phthisis bulbi without rupture. It may be bilateral, but it never causes sympathetic ophthalmia.

You will thus see that the eyeball, its position and condition, especially that of the media, will soon show you, with the history of the patient, that it is metastatic panophthalmitis with which you have to deal, and not orbital cellulitis *per se*. True it is that orbital cellulitis may cause by strangulation of its blood-supply complete mortification of the eyeball, but it is exceedingly rare, and I have never seen it. But it is a last result only and therefore does not come into our region of diagnosis.

Now the fat of the orbit varies somewhat, not only in form and consistency, but also in amount. In the outer and lower half of the orbit you will find it firm and compactly enclosed in compartments of fairly dense strands of connective tissue, whilst that surrounding the sheath of the optic nerve is looser, more finely fibrillated, and more oleaginous, and only becomes firmer and has thick fibrous strands in the intermuscular intervals. A knowledge of this is very important, as in cases of periosteal trouble, where cellulitis is quite secondary, and pus easily riddles and absorbs this thin fat; the pus is far back around the nerve, whilst in the upper and outer and lower portions of the orbit, where the fatty tissues are much more compact and firm, they are but slightly affected by the exudation of inflammatory products. You will remember that the eyeball rotates by a complicated mechanism in which Tenon's capsule plays quite a secondary part. The fatty tissues and muscular cone move as a whole at the same time that the eyeball moves in Tenon's capsule. Now a knowledge of this helps us in diagnosing the probable cause of orbital cellulitis in periostitis, panophthalmitis, and so-called idiopathic cases. For in periostitis the eye is generally well deviated to the opposite side of the lesion, and is capable of motion in a certain direction without much pain. But pain is very severe on even the gentlest pressure backward or to the side of the lesion, and when the typical boring pain of bone disease comes on at night the eye may be observed to rotate. In panophthalmitis the affection of Tenon's capsule causes the eye to be rigidly fixed in the median line and no motion of the eyeball is possible, owing to acute tenonitis and the general involvement of the whole of the orbital tissues. In idiopathic cellular inflammation, whilst there is not much, if any, mobility of the globe, the lids are uniformly and intensely congested, and no one part of the orbit is more markedly affected than elsewhere, as is often the case in periosteal disease, and the eyeball and Tenon's capsule are nearly natural.

### TUMOURS AND SWELLINGS OF THE ORBIT.

In considering diseases of the orbit it is well to remember that the actual cavity of the orbit, the eyeball of which normally occupies only one-fifth, may be either expanded, as it is in long-standing intra-orbital disease, or contracted by being encroached upon by tumours and swellings from without or within the skull. It is surprising how much pus it can contain in the living subject or how many years a foreign body may be lodged in it without causing trouble.

I show you here the photograph of a child (Fig. 1) who had a lympho-sarcoma of the left lacrymal gland which weighed 2¾ ounces and had greatly expanded the orbit on that side, although there was no infiltration of the orbit—for you will remember that there are no lymphatic vessels in the orbital tissues—except the lids and conjunctiva. Here is another, of a girl also, who had the capacity of the left orbit very greatly encroached upon by a large exostosis of the temporal bone, and the proptosis that is present is due to it; the eyeball is normal, the vision good, and mobility free, but there is diplopia in certain positions. When the orbit is invaded by malignant growths from the skull, especially those arising from the sella turcica in that region, they do not have time to expand the orbit, but cause rapid proptosis without much pain. Morax had a most valuable case in 1904 of sarcoma of the temporo-sphenoidal lobe in a man of 40 in which a process of the growth had penetrated through the temporo-sphenoidal fissure into the right orbit, and which, besides causing marked proptosis, homonymous hemianopsia, and a relative hemiopic pupillary inaction, with retained normal vision, had the peculiar sensations of perverted smell. The patient died six months later, and although the hemiopic pupillary signs remain permanent the necropsy showed that mere pressure on the optic tract was sufficient to cause the symptoms without there being evidence of structural alterations, as careful staining of the tract and visual centres revealed the parts to be normal.

Of the slowly growing swellings of the orbit we have chiefly chronic periostitis, abscesses, exostoses, gummata of the soft parts, and the cysts and new growths. Chronic circumscribed periosteal abscess, in my experience, takes place in three situations: either it is along the inner wall or at the apex, and then it is in persons under 35, and the patients are kept awake at night by pain and eye-ache; or it

FIG. 1.

Lympho-sarcoma of the lacrymal gland.

occurs in persons of about 40 years of age or older, and then is situated in the middle line of the orbital plate of the frontal bone, just behind the overlapping bony rim. Here it causes a characteristic tumefaction of the centre of the upper eyelid and eyebrow, perhaps is tender, but not often painful, and does not interfere with orbital structures or the ocular movements. When the extreme rim of the orbit is attacked it is generally in children with a scrofulous or traumatic history, and occurs at the outer part over the lacrymal gland or malar bone. Exostoses, if not too deeply situated, are fairly easily diagnosed by their extremely slow growth, nodulated surface, if this can be felt, and ivory hardness. They arise mostly from the sutures or in the sinuses, are deeply situated, and at first cause but little trouble, but later optic atrophy and proptosis, and may necessitate excision of the eyeball. They are painless in the early stages. I excised one from the rim of the orbit in the region of the orbital notch recently. You will find in deeply seated tumours of the orbit that it is very seldom that one can satisfy oneself as to the nature of them. The only possible way to palpate them is to thrust the smallest finger firmly but gently into the conjunctival sac after instilling cocaine. Valuable aid may be obtained in this manner. Orbital tumours may be solid or cystic, innocent or malignant.

Solid tumours of the orbit are much more deeply seated in my opinion than the cystic. They are fibromata; lymphomata which are often symmetrical and associated with lymphatic nodules in other organs of the body; endotheliomata and sarcomata. Carcinoma has only been found as metastatic growths and is extremely rare. The fibromata, lymphomata, as well as the lipomata, which latter are mostly seated anteriorly at the upper and inner angle, are all of them slow-growing, benign, painless, and tenderless swellings which cause slight proptosis and diplopia but nothing more. On the other hand, a patient who comes with a sarcoma comes complaining of pain in the orbit or eyeball, or both, and has tenderness on pressing back the orbital contents, and he will tell you that he is conscious of having "something growing behind the eye." Sarcomata early invade the orbital muscles and interfere with the ocular movements by invasion long before pressure does (Fig. 2) But some of the sarcomata, which arise in or about the

sheath of the optic nerve, and which cause proptosis straight forwards, because they are within the cone of muscles, cause early optic atrophy and amaurosis, are less malignant, and do not grow so rapidly or have so great—if any—tendency to spread to the muscles. Many pathologists now classify these tumours, which were formerly called myxofibromata, among the endotheliomata, because Treacher Collins and others have found no mucoid or myxomatous substance in the cases they have examined, but only general œdema of the tumour.

There is a chronic hyperplasia of the tissues about the optic nerve and of the interstitial substance in old syphilitic patients, especially those who are the subjects of cerebral syphilis and pachymeningitis, which may cause not only proptosis, optic atrophy, and blindness, but pain also. This pain is associated with other morbid cephalic sensations, and is probably part of the pachymeningitis or periostitis. The nerve may be three or four times its normal thickness and very hard. Some tumours of the optic nerve have grown so slowly as to cause flattening of the antero-posterior pole of the eye, and with resulting hypermetropia.

The diagnosis of cold and slowly-growing swellings of the orbit is largely aided by a knowledge of embryology. You will find meningoceles and encephaloceles nearly always at the fronto-nasal process, and very rarely along the ethmoid. They are congenital, smooth, swell on coughing and crying, and may be emptied by gentle pressure. They do not call for surgical interference as the patients are the newly-born, very debilitated, and soon die. The dermoids are generally either at the upper and outer angle of the orbit or at the inner wall, or on the eyeball itself. They may contain teeth, but I have never known them contain more than hairs and sebaceous matter, or an oleaginous and green fluid. There is a case, I am informed, at Leipsic University, of a teratoma protruding from an orbit, apparently a limb, but these cases are mere curiosities.

Dermoids of the orbit are smooth, nearly circular, semi-solid, mobile swellings which always appear more superficial than they really are; and in two of my cases where the growths were along the inner wall they sent long bands of

FIG. 2.

Sarcoma of orbit.

firm tissue backwards, and in one case a process went under the internal rectus muscle which had to be divided at its insertion and afterwards re-attached in order to thoroughly extirpate the growth. Great care is necessary in operating upon these dermoids, as sometimes the processes project into the cranial cavity, or through the sinuses, or are attached to large veins. But they are quite operable, and leave the eyeball and orbit with no defect worth mentioning afterwards, either functionally or cosmetically. There are not 20 hydatid cases on record and only half that number of cysticerci; they fluctuate and grow slowly. Filaria loa has occurred. The two other cysts that are not uncommon are the dacryops, which is easily diagnosed, since it is a lid tumour and can be found connected with the lacrymal gland, a duct of which has become enormously distended. Sometimes fluid may be squeezed from it. The other is a congenital cyst presenting along the lower eyelid, pushing it forward, and projecting also well backwards beneath the eyeball. It is connected with the globe and sometimes with the vitreous, and has arisen from the defective closure of the choroidal fissure. I here show you the section of such a cyst and the eyeball which I removed three years ago. My colleague, Mr. Brooksbank James, has a beautiful case attending the hospital now, in which the ophthalmoscope shows a connexion between the cyst and the eyeball.

The swellings in the orbit most likely to be confounded with the cysts in the early stages are the vascular tumours—the nævi and nævo-lipomata and the arterio-venous aneurysm. The nævi take two forms—the soft compressible, and the firmer, which may be slightly cystic. The first are by far the commoner, and may be connected with the veins of the lids, but are generally entirely within the orbit, and arise within the cone of muscles above or below the eyeball, and rarely to the nasal side, and protrude between the muscles into the orbit, projecting beneath the conjunctiva. They are all encapsulated, lobulated, and swell up on forcible expiration or on drooping the head forwards. They can be partially emptied on pressure, are not painful or tender, and do not interfere with the eyeball movements. They appear first at puberty and take years to grow, but cause great, quiet proptosis and distort the anatomy of the parts without loss of vision. The more solid ones have no impulse or expansion upon coughing or lowering the head, but they contain old and organised blood-clots, many large calculi, and sometimes small cysts. Some of you have no doubt seen the girl whose photograph I here show to you. She is 14 years of age, has large symmetrical nævi of the upper eyelids projecting into the orbits, which swell up greatly on lowering the head for a few seconds. The mother states that they are much larger and firmer at the menstrual periods. I intend to operate upon both of these.

In cases of arterio-venous aneurysm, or aneurysm of the internal carotid, or aneurysm of the extra-orbital portion of the ophthalmic artery, there is, even in the earliest stages, a continuous bruit, of which the patient is conscious, and which you can hear with the stethoscope. The patients nearly always give you the history of "something having gone off bang" in the skull, and they state that they continually hear the noise afterwards; it even keeps them awake at night. But they only come to you days or weeks later, when proptosis and chemosis of the eyeball appear. If you lay the flat of your hand on it you can feel it pulsate and expand. There is sometimes pain, but the sight is retained until very late in the disease. The patients generally give a history of syphilis or trauma. Sometimes a large venous dilatation will give pulsation and a bruit, but the great point to remember is that the bruit intermits in venous cases, there is no chemosis, and the contents of the orbit are more compressible, not painful, and the patient is not conscious of noise in his head.

Lacrymal gland tumours sometimes grow to a great size before they cause symptoms or physical signs. They mould themselves to the deep recess behind and above the outer rim of the orbit and at first extend backwards; afterwards the hard, sharp, and sometimes notched edge can be felt through the upper eyelid. They are rarely tender or painful unless inflamed, but sooner or later cause displacement of the eyeball and contents of the orbit downwards and inwards with enormous stretching of the upper eyelid. The photograph I showed you is one of a girl, aged 12 years, with marked orbital distension and proptosis caused by a lymphosarcoma of the left lacrymal gland. The pre-auricular gland, as well as the parotid lymphatic glands on that side of the face, were much enlarged. I excised the growth, which weighed 2¾ ounces, and the glands, and the patient did well and returned home. But four months later the patient had a recurrence of the cancer in the pharynx and parotid, from which, I was informed, she died, but it did not recur locally. The commonest swellings of this gland are either simple hypertrophy or endotheliomata. Excision is the treatment. Whilst it is almost unknown for tumours of the orbit to invade the eyeball, the reverse is by no means uncommon. They may perforate the globe at any site by thinning and absorbing the sclerotic, but the commonest place is by invading the optic nerve, or through its foramen in the sclerotic, or they perforate the limbus to the outer side of the cornea after causing glaucoma, and present as one variety of the fungus hæmatoides described by Wardrop. They are nearly all cases seen in quite young children and are gliomatous, and it is a late

stage of the disease when they are first seen by the surgeon, but the soft and thin state of the sclerotic coat in children, which easily yields to internal tension, predisposes to orbital extension. The photograph of the case I show of an enormous tumour projecting from the left orbit of a little Chinese girl was one of secondary recurrence after excision of the globe for perforating glioma of the retina.

Lastly, I wish to refer to some cases that I have seen at odd times of obscure and recurrent pains in the orbit, in which there has been no definite swelling, or proptosis, or tenderness, or which, if present at all, has been quite transitory and lasted less than 24 hours. One class of cases belong to the category of so-called ophthalmoplegic migraine and is associated with hemicrania, giddiness, slight ptosis, and perhaps paralysis of an extra- or intra-ocular muscle. They occur in youth, and patients get well upon alterative treatment, and about a year later recur. Then there is another in the so-called angioneurotic œdema, but here there is some slight swelling of the lids, which in one case occurred upon excitement after dancing or going to a theatre. Lastly, some rheumatic patients get intractable pains in the orbits which are quite independent of errors of refraction and muscular anomalies. They may be due to our old enemy, a sinus, especially the sphenoidal, and this is not improbable if the pain is deeply situated between the eyes. There are other sets of orbital cases, such as exophthalmic goitre, the cases of increased intracranial pressure with proptosis; the cases of tenonitis, the cases of enophthalmos which I should have liked to discuss, but my allotted time for this lecture has run out, and I must close.

# TRANSVERSE FRACTURES OF THE PATELLA, WITHOUT SEPARATION OF THE FRAGMENTS.[1]

BY A. E. JOHNSON, M.B. VICT., F.R.C.S. ENG.,
RESIDENT MEDICAL OFFICER, MIDDLESEX HOSPITAL.

THE causes of separation of the fragments of a transversely fractured patella, and the causes of failure to obtain bony union in cases in which much separation has occurred, have been of the greatest interest to surgeons for some considerable time. The subject was first studied scientifically by Gulliver (1), whose classical experiments laid the foundation of our knowledge of this subject. He performed 11 experiments on dogs and rabbits, in five of which he divided the patella transversely together with its aponeurosis, and in the other six divided the bone only, leaving the aponeurosis intact. In the five in which the aponeurosis was divided there was separation of the fragments, and only fibrous union resulted. In the six in which the bone only was divided there was no separation of the fragments, and firm union was the result in all. The union was bony in five of these cases, but in one patella, removed only 27 days after the experiment, there was short ligamentous union only and no new osseous tissue had appeared. Amongst Gulliver's conclusions we find the following: "Osseous union is simply the effect of immoveable coaptation of the fragments, the provision for which, in certain forms of fracture, is the integrity of the aponeurosis in front of the bone." Gulliver, therefore, so long ago as 1837, only just failed to grasp fully the pathology of the failure of bony union in most of these cases. He knew that the rupture of the aponeurosis was the primary cause, but missed the fact, observed and pointed out by Macewen (2) nearly fifty years later, that the aponeurosis does not give way opposite the seat of fracture, with the result that the fringe attached to one part, generally the upper, falls between the fragments.

Macewen's clinical observations established the fact that the interposition of the præpatellar fibrous structures between the fragments was the cause of failure of bony union, and his deductions from his observations drew a picture of the pathology of transverse fracture of the patella which has been amply borne out by later observations made with greater facilities. Since the introduction of the X rays further proof has been forthcoming, and the recognition of transverse fractures, without any separation of the fragments which could not be diagnosed with certainty before the days of skiagraphy, has furnished additional evidence of the truth of Macewen's statements.

From the ease with which such fractures can be missed and the frequency with which they are found when specially looked for, one is led to infer that before the introduction of the X rays many cases without separation of the fragments were not diagnosed at all, or only after a further trauma had "completed" the fracture. Support is given to this view by the following. Malgaigne (3) described the case of a man who, several years earlier, broke his left patella, and in February, 1839, fell and broke the union. In March, 1839, he died, and at the post-mortem examination it was found that the right patella had also been broken and united by bone. This fracture of the right patella had not been suspected during life, and Malgaigne's drawings (4) show how close the union was. Again, Broca (5, 6) described a case of fracture of the patella by direct violence in which the fragments were held together for 14 days, when a false step and the slight muscular exertion necessary to prevent a fall led to tearing of the aponeurosis and separation of the fragments. Broca also quotes two similar cases reported by Malgaigne. In one of them a medical man received a violent blow on the knee from the wheel of a carriage and continued to walk, but the next day, whilst descending a staircase, he slipped, made an effort to recover himself, and the fracture was "completed." In the second case a woman, who had a violent contusion on the knee, continued to walk, and at the end of a month, whilst making a slight exertion, separated the fragments.

Broca's case is of special interest, in that there was positive proof that the first fall really did lead to a fracture of the patella by direct violence, for at the subsequent operation it was found that the lower fragment was split into two halves, the strain at a later date having caused separation at the site of the transverse fracture.

In 1887 Macewen (7) himself related an interesting case. A young medical man received an injury to his knee in a football match. He could, however, walk without much difficulty. On examining his patella no line of fracture could be found. Still, osseous crepitus was detected on lateral movement. The patient went about with a bandage applied for three weeks. Firm bony union took place. Macewen first saw the limb some years later, when there was only a transverse ridge on the patella to mark the seat of the former fracture. After describing this case Macewen expresses the opinion that "it is highly probable that those specimens which are occasionally seen of osseous union after transverse fracture of the patella have been obtained from patellæ which were fractured without accompanying rupture of the præpatellar ligamentous structures," an opinion which has been endorsed since the introduction of the X rays and the frequency of the occurrence of such fractures has become more apparent. I would here mention a case reported by Vallas (8) in 1899, in which a man fractured his patella by direct violence and became unconscious. He therefore made no attempt to rise, and there was no separation of the fragments. No operation was performed. In 1905 the same man died from Ludwig's angina, and the patella was obtained. It was described by Vallas (9), and it was impossible to find a solution of continuity either by direct examination or by the X rays.

Since the use of X rays has become more of a routine measure in cases of possible fracture a few further remarkable cases have been reported, the most striking being three described by Wegner (10), who, by employing the X rays systematically in all cases of injury, was able to demonstrate some cases of fracture of the patella which had not been diagnosed before. Since they were the first cases of this nature which had been clearly described and demonstrated by skiagrams, I venture to quote them rather fully, especially as at present they are only on record in the German language. They are of the greatest interest when studied with some cases of my own which, as far as I have been able to find, are the only other similar cases clearly demonstrated.

In Wegner's first case a man, aged 35 years, slipped and "wrieked" his knee. He did not fall, and after walking about 20 paces in considerable pain he was driven home. His medical attendant diagnosed an internal derangement, and treated it for four weeks with fixation, and then adopted massage. Two months after the accident the patient returned to light work, but had to abandon it, and four months after

[1] A paper read befor the Surgical Section of the Royal Society of Medicine on Dec. 13th, 910.

the accident he went to hospital. There was some atrophy of the thigh muscles, but the patella could be easily moved, was not enlarged nor uneven, and movements in the knee were free and without grating. A skiagram revealed a transverse fracture of the patella, and the plate which Wegner publishes shows that there was practically no separation of the fragments. With massage and exercises the muscles were restored and a good result was obtained.

The second case was that of a workman, aged 41 years, who is stated to have fallen on his left knee as he was carrying a chest of drawers downstairs, thinking he had only one instead of two stairs to go down. He walked home in spite of acute pain in the knee, stayed in bed for one day, and then went a 12-minutes' walk without stick or other help to see the surgeon, having to ascend two steps to get to the house. He walked home again alone. He was admitted to hospital three days after the injury. The effusion which was present disappeared after four weeks' compression, but on account of pain on the inside of the knee a further examination was made, and it was decided that the patient had a loose body in his joint. A skiagram, which Wegner publishes, was taken to decide this point, when it was found that the patient had also a transverse fracture of the patella, with practically no separation of the fragments, although a careful examination had failed to detect any pain at the site of the fracture, or any crack, or any separate mobility of the fragments. The patient had had no difficulty in extending the limb or raising it from the splint. The loose body was removed and the patient made an uninterrupted recovery. Bony union occurred, and on the X ray plate, with the exception of a small eminence on the anterior surface of the patella, Wegner states that there was no trace of injury.

The third case reported by Wegner is that of a workman, aged 44 years, who struck his right knee against the rung of a ladder which he was ascending. He felt a crack, but, in spite of acute pain, went a seven minutes' walk and ascended three storeys to his room, descended again to see the surgeon, again ascended, and two days later, on the advice of his medical attendant, went to hospital, again descending the three storeys alone. With the exception of a slight bruising of the soft parts at the sides and in front of the patella there was no sign of injury, and no sign of fracture of the patella, though this was specially looked for. A skiagram, which Wegner reproduces, shows the presence of a transverse fracture of the patella near its middle, without separation of the fragments. Treatment consisted of enclosure in plaster-of-Paris for six weeks, after which massage and exercises were employed. Convalescence was uninterrupted, and after three months Wegner states that no signs of a fracture could be detected by the X rays.

In 1900 Barker (11, 12) showed a somewhat similar case at the Clinical Society. This was a case of fracture by direct violence, with no palpable displacement, which was discovered by the aid of the X rays. The plate which was published, however, shows a separation of about a third of an inch, which is much more than in Wegner's cases or my own. Cauthier (13) reported a case of transverse fracture of the patella due to direct violence, without appreciable separation of the fragments, in which it was not until the man had been under treatment for eight days that a fracture was diagnosed. Cases which fall into the same category have been mentioned also by Thiem (14), Mayer (15), Doberauer (16), Smith (17), and Humblet (18). Trésoret (19, 20) has also reported a case of fracture by direct violence which should be included amongst those we are considering, for though the man went about his usual work in the field, walked two kilometres directly after the accident, and 13 kilometres the next day, he did not seek advice for more than two months afterwards, yet the union between the fragments was so narrow that it only measured some lines in breadth.

Blackham (21) has reported a case where the lower tip of the patella was broken off without the fragment being separated from the main part of the bone; and Bennett (22) showed at the Dublin Pathological Society a specimen obtained from the dissecting-room in which the same thing had occurred, though there was no history to the case. In Scudder's book (23) there is a tracing of an X ray plate of a similar fracture. In these cases of fracture of the tip of the patella the line of fracture is extra-articular, and separation of the fragments seldom takes place, since at this point the bone lies in the thick and strong patellar tendon. They have been fully described by Rödiger (24). Such fractures are very rare and of but little importance compared with transverse fractures through the body of the patella without separation of the fragments. The fractures of the tip of the bone get well without treatment; whereas in fractures through the body of the patella there is danger of some slight muscular exertion at a later date leading to separation of the fragments. Moreover, the joint being involved makes the injury a more serious one.

An extraordinary variety of transverse fracture of the patella is referred to by Reichel (25) and Magruder (26) in which the fracture is incomplete, not involving the cartilage. I have never seen a skiagram of such a case, which, of course, could not be diagnosed without the use of the X rays, and there do not seem to be any published. Such cases would be very like cases of incomplete fracture of the olecranon, which I have described elsewhere (27, 28), but if an incomplete fracture of the patella does occur it is much more remarkable than a similar injury to the olecranon. It must be remembered, however, that it is easy for the fracture to appear incomplete in a skiagram when the fissure does really extend through the whole thickness of the bone, and a careful examination with the screen should be made before the plate is exposed in order to avoid the chance of this error being made.

Now it is, of course, well known that cases of fracture of the patella from direct violence often do not result in much, if any, separation of the fragments. These fractures may be of any nature and the line of fracture may be in any direction. They are often comminuted, sometimes vertical, and in many cases transverse. It is not a matter for surprise, therefore, to find no diastasis in transverse fractures of the patella if due to direct violence, as in Wegner's last two cases and in other cases which have been quoted.

As in many ways a fairly typical example I will mention a case which occurred in the practice of the Middlesex Hospital.

CASE 1.—The patient, an able-bodied man, aged 28 years, was descending some steps into the street on May 26th, 1909, when he slipped and fell on his left knee. He got up without help and walked half a mile without stick or aid of any kind. On attempting to walk again, after resting for half an hour, he had much pain in the knee, and had to obtain the help of a friend to walk about a quarter of a mile to the hospital. He was seen by one of the resident officers, who transferred him to the out-patient department as a case of "traumatic synovitis" of the knee. The surgeon who saw him suspected the possibility of a fracture of the patella and recommended him for admission. The patient could move the knee freely, there was no palpable separation of the fragments, and no crepitus was obtained. A radiogram (Fig. 1) revealed a fracture of the patella without separation of the fragments, the line of fracture being mainly transverse, but the bone being slightly comminuted. There was considerable effusion into the joint and the patient was kept in bed for a few days, after which he had a light removeable plaster-of-Paris splint applied and went to the convalescent home. There massage and passive and active movements were carried out daily, and convalescence was uninterrupted. Bony union occurred, as the accompanying skiagram, taken on Dec. 20th, 1909 (Fig. 2), shows, and the man recovered with a strong knee and perfect movement.

This case, as I have said, is fairly typical and by no means uncommon, though, like many similar cases, it presented some difficulty in diagnosis. But the next three cases I will describe were much more remarkable and of the greatest pathological, as well as clinical, interest, for the fractures were caused in each case, as in Wegner's first case, by indirect violence—that is, by muscular contraction snapping the patella across the lower end of the femur—the well-named "tear fracture" of the patella.

CASE 2.—The patient, a man aged 43 years, a driver of a horse tramcar, was descending the stairs to open the door to some visitors on the evening of Jan. 15th, 1909, when he caught the heel of his boot on the edge of a stair. He stumbled, but with an effort recovered his balance. He noticed a slight pain in the right knee, but did not pay any attention to it, finished his descent of the stairs, and returned to his room, mounting two storeys. Next morning he noticed that his knee was rather swollen, but went to work. Owing to some pain and weakness in the joint he came later in the day to the hospital. He walked in with a slight limp, and, on examination, it was found that there was a little effusion into the joint, but otherwise no sign of any injury. The history being very suggestive of a fracture of the patella, particular attention was paid to the signs of this injury, and he was seen by several members of the hospital staff. There was no crepitus, no local tenderness, no cleft could be felt, no interference with movement (apart from what would be accounted for by the effusion alone), and no loss of the power of extending the leg. A radiogram, however, revealed the presence of a transverse fracture of the patella without separation of the fragments (Fig. 3). The patient was kept at rest in bed for a few days, when a light moveable plaster-of-Paris splint was applied, and he was sent to the convalescent home, where he had massage and exercises daily, getting about during the rest of the day with his splint on. Convalescence was uninterrupted and bony union the result. (Fig. 4, taken on Feb. 14th, 1910.)

This last case was demonstrated at a meeting of the Middlesex Hospital Medical Society on March 25th, 1909, and the importance of being on the look-out for such an obscure injury was emphasised. It was somewhat alarming a few weeks later, when a house surgeon informed me that he had filled the last surgical bed with a traumatic synovitis of the knee, because he suspected that it might turn out to be a case of a similar fracture to the one I have described. However, my fears that the wards would be filled with cases of suspected fracture were not justified, for the case turned out to be a transverse fracture of the patella without separation of the fragments. The history of the case is as follows:—

CASE 3.—The patient, a barmaid, aged 29 years, was turning round quickly in a stooping position when she felt a pain in the left knee like "something stretching." The pain increased, so she went to get some camphorated oil, her panacea for all ills, to obtain which she ascended

three flights of stairs. She then returned to her work at the bar, but as the knee got more painful she sent for a medical man, who referred her to the hospital. She was admitted to the Queen's Ward on April 14th, 1909, the day of the accident, under Sir Alfred Pearce Gould, who, knowing I was interested in these cases, kindly transferred the patient to my care, and I am indebted to him for permission to publish it. There was good power of extension of the leg; no line of fracture could be felt. There was no local tenderness, no crepitus, and but little effusion into the joint. A radiogram (Fig. 5) showed a transverse fracture of the patella, without separation of the fragments. After a few days' rest in bed a light removeable plaster-of-Paris splint was applied, and she was sent to the convalescent home, where massage and passive and active movements were carried out daily. Convalescence was uninterrupted and the result was excellent, bony union occurring, as the accompanying plate shows. (Fig. 6, taken on Sept. 5th, 1909.)

CASE 4.—The remaining case was that of a carman, aged 31 years. He was descending some stairs on Feb. 7th, 1910, to deliver a parcel, when he slipped and fell downstairs, failing to recover himself. He did not fall on his knee, but his leg was bent under him. He got up, went upstairs again, mounted his van, and drove back to the depôt. He got off his van without help. The knee later in the day became painful, so he drove round to the hospital and walked in. The case was diagnosed as one of synovitis of the knee, a back splint was applied, and the patient instructed to attend as an out-patient. The next day he remained indoors, but the following day, Feb. 9th, he called at the hospital again, when the casualty surgical officer, Mr. C. H. S. Webb, ordered a skiagram to be taken (Fig. 7), and it was found that there was a transverse fracture of the patella, without separation of the fragments. In this case, as in the others, there was no local tenderness, no crepitus, and no separation of the fragments to be felt. The power of extending the leg was quite strong also. The same treatment was adopted as in the other cases and the result was excellent, bony union being obtained. (Fig. 8, taken on July 18th, 1910.)

For the trouble he has taken in the skiagrams published with the above cases I am much indebted to Mr. R. F. Mann, photographer and assistant in the electrical department at the Willesden Hospital.

The problem of the satisfactory treatment of fractures of the lower limb in hospital is no easy one, for if they are to be treated by massage and exercises these cannot be carried out for a sufficient length of time in the wards owing to the great demands on the beds, so that some splint has to be applied while they are being treated as out-patients, with the result that stiffness in the neighbouring joints and adhesions at the site of fracture are but too common. At the Middlesex Hospital a serious attempt has been made to deal with this difficult problem, and we are fortunate in having at our convalescent home a most able and enthusiastic matron who takes the greatest interest in these cases, and supervises treatment by massage and exercises by nurses skilled in massage after the patients are fit to be discharged from the wards of the hospital.

All the cases of fracture of the patella which I have described were, after a few days' stay in bed, transferred from the hospital to the convalescent home, where massage and movements were carried out daily. In all the cases recovery was absolutely complete—in fact, a perfectly sound limb was the result, and the patients were fit to return to their occupations within three months of the date of the injury.

In every instance the union was bony. Unless great care be taken to make the exposure to the X rays in the exact line of fracture, it is quite possible for a plate to appear to show bony union when none is present. In all my cases the patella was most carefully examined through the fluorescent screen before the exposure of the plate, to make absolutely certain that no cleft between the fragments was still visible.

The cases are extremely interesting in many ways. First, they are of great pathological interest, for they bear out very clearly the statements of Macewen with regard to the mode of production of a transverse fracture of the patella by indirect violence. As Macewen (29) stated, "the fibrous and aponeurotic tissues lying in front of the patella are more elastic than the bone. By muscular action the bone snaps and retracts, and the fibrous and aponeurotic tissues over it still holding they bridge the interspace between the two fragments. If the contraction continues, the aponeurotic and fibrous tissues become overstretched and lose their resiliency. Finally, if the force be great enough the bridge gives way ....."

The clinical interest of these cases is enormous, and their importance cannot be exaggerated. The fact that the patients walked without much difficulty is remarkable in itself. Still, it must be remembered that patients can walk even when there is an obvious fracture of the patella, with marked separation of the fragments. Jessop (30) reported the case of a bargee who broke his patella clean across, tied a handkerchief round the knee, but never lay up or received any treatment at all. Dubrueil (31) also relates how a man fractured his patella and was able to walk forward to his home. Later he re-fractured it and again was able to walk. Martin (32) has also reported a similar case; while Carl Beck (33) mentions that in his experience patients, in spite of appreciable diastasis, were able to walk considerable distances without apparent discomfort. The fact that a patient walks in to see the surgeon should not therefore lead him to exclude the likelihood of a fracture of the patella having occurred.

From a study of these cases without separation it will be realised that the diagnosis may be extremely difficult, and that an absolutely certain diagnosis may be impossible without the aid of the X rays. This possibility has been rather neglected in most text-books, though recently attention has been called to it in some American and German works. Besides those writers who have already been referred to, these cases of fracture without separation of fragments have been mentioned specially by Reichel (34), König (35), Magruder (36), and Heineck (37), the last named stating that they often escape recognition. But even in the latest work by Cotton (38) it is stated that tear fractures always lead to separation of the fragments. This is shown to be a misstatement by Wegner's first case and by my three cases.

The difficulties of diagnosis being proved, the question arises whether neglect to recognise cases of this character is of great importance. Undoubtedly it is. If these cases are treated as simple contusions or sprains, and the patients are allowed to go about and return to their ordinary work when the swelling has subsided, separation of the fragments is likely to occur, and the fracture may be very easily converted from one which will get quite well with rest and care into one requiring operative treatment to ensure a satisfactory result. The case reported by Broca, and Malgaigne's cases which he refers to, all of which I have already described, are good examples of the dangers to which these patients are exposed. It is essential, then, in injuries of the knee or any other part to have a skiagram taken of all cases in which there is the slightest possibility of fracture. In fact, the X rays, by the revelations they have made, have proved the importance of having a plate taken in all injuries of the joints, and there can be little doubt that many cases diagnosed as sprains are really associated with fracture. The medico-legal importance of these cases can hardly be over-estimated, for if the patient obtain a skiagram elsewhere, which shows a fracture when the surgeon has assured him that there is none, the consequences are likely to be extremely unpleasant, if not disastrous, for the surgeon. While not in any way wishing to discourage the most careful manual examination of cases of injury, the fact must be recognised that manual examination, however carefully carried out, will fail to demonstrate some bone lesions which only the X rays will reveal. By the systematic use of the X rays obscure injuries will be revealed, and much needless suffering and inconvenience prevented.

The next aspect of these cases to which I will direct attention is the process of repair and the importance of obtaining bony union. The average length of treatment in my cases was about three months, when the patients returned to full work. Skiagrams were frequently taken to make sure that no separation of the fragments was taking place. The new bone does not throw a clear shadow for some months after it is laid down, and it is not possible to be sure that bony union has occurred until five or six months after the injury. I attach great importance to obtaining bony union in these cases, for even a short fibrous union is liable to stretch, an occurrence attended by some disability, not to say many dangers. Not the least of these dangers is the liability to re-fracture of the patella or rupture of the ligamentum patellæ. It is a pity, to my mind, that cases of fracture of the patella, including even those which have been submitted to operation, are not more carefully followed up and skiagraphed to see whether bony union has resulted; and Stimson (39) has stated that even in operation cases the union, which was so close that no independent mobility could be recognised, has sometimes been found to be fibrous, while in some bony union has taken place only in the posterior half or three-quarters.

It has been maintained that fibrous union was as good as, or even better than, bony. Hamilton (40), for instance, stated that a fibrous band, with only half or three-quarters of an inch separation, was as useful as bony, whilst many writers contended that because the bone, and not the fibrous

FIG. 1.

FIG. 2.

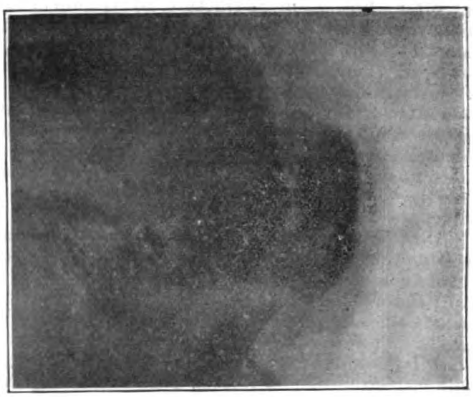

FIG. 3.

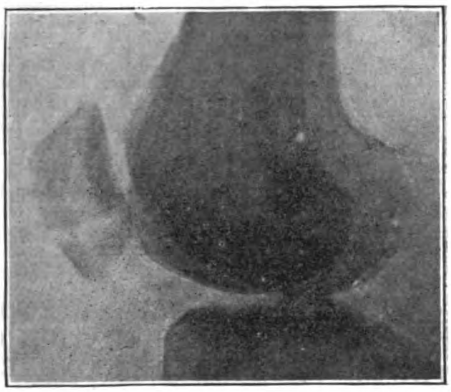

FIG. 4.

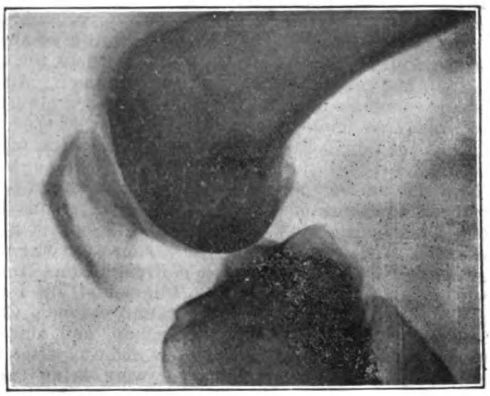

FIG. 5.

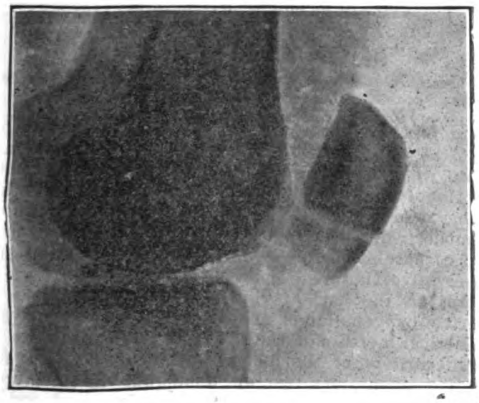

FIG. 6.

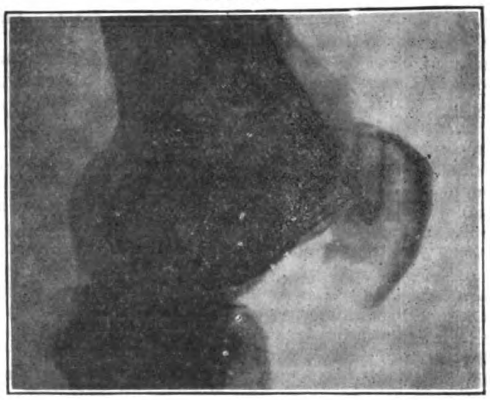

FIG. 7.

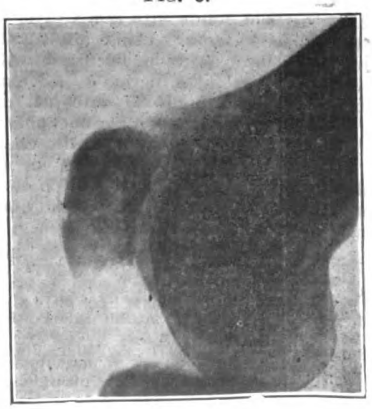
FIG. 8.



union, often breaks in re-fracture, bony union has no advantage over a close fibrous union. Such was maintained by Morris (41), Desprès (42, 43), Wagner (44), and Murray (45), amongst others, but these surgeons were probably not aware of the fact that re-fracture was more common after non-operative than after operative treatment, and that it was the fibrous union and consequent lengthening of the patella which predisposed to re-fracture.

That fibrous union of a fractured patella does seriously impair the stability of the knee-joint must now be undoubted. Re-fracture is much more frequent in the patella than in any other bone—Lauper (46), Thiem (47), Corner (48, 49); and more common after massage and other forms of non-operative treatment (when the union is generally fibrous) than after open operative treatment (when the union is probably bony)—Alessandri (50), Gibbon (51), Meyers (52), Powers (53), Bégouin and Audérodias (54). Not only does a fibrously united patella increase the liability to re-fracture, but the whole extensor arc is weakened, the joint being uncertain and unreliable, which leads to frequent falls if the patients return to their usual occupations and habits of life. There is evidence of this in the frequency with which other injuries occur; for example, rupture of the ligamentum patellæ. In 140 cases of rupture of the ligamentum patellæ Walker (55) found that previous fracture of the patella had been an etiological factor 17 times. Although bony union presents but slight advantages over a close fibrous union so far as immediate results show, when the future history of the limb is taken into account the advantages are much greater.

The period of treatment in my own cases might possibly have been cut down slightly, but, for the reasons I have stated, I was particularly anxious to make sure of a sound bony union. There has been great keenness on the part of surgeons to cut down the length of treatment of fractures of the patella after suture of the fragments, but I cannot help thinking that this has been rather overdone. Cases of re-fracture after wiring are too common, and since they generally occur during the first few months after operation it looks as if too great a risk were being taken in allowing these patients so much freedom of the limb, and some support such as a bandage or even some check apparatus, such as that described by Howard Marsh (56), would seem advisable to prevent extreme flexion for the first few weeks after getting about. No doubt, however, many wonderful cases have been reported; for instance, one recorded by Lucas-Championnière (57), where a clown was able to return to his occupation, involving the turning of somersaults, within two months after operation.

In bringing the subject of transverse fracture of the patella, without separation of the fragments, under notice, I thought it would give food for thought in many ways: pathologically the cases are interesting; the clinical picture is most striking and teaches us to hesitate very much before giving a definite diagnosis of a bone lesion without the help of the X rays; and historically, in accounting for probably most of the cases of bony union which were recovered from the post-mortem and dissecting rooms before the days when wiring was the usual treatment.

By far the most important point for the surgeon is the difficulty of diagnosis, and he must now realise that he is absolutely dependent on the X rays in such cases. With regard to the frequency with which these cases occur, it is difficult to speak with certainty, and until it is the rule to examine all injuries of joints with the X rays, we cannot say how many of these cases are being missed at the present time. The cases I have described occurred in the practice of the Middlesex Hospital in a period of 13 months, during which time we treated in all 20 cases of fracture of the patella. Failure in diagnosis may not only involve the surgeon in a suit for damages, but if the character of the injury be not realised by somebody else, an unusual strain may lead to great hardship for the patient, owing to separation of the fragments and the necessity of an operation which would otherwise have been unnecessary.

Middlesex Hospital, W.

A CASE OF

# CONGENITAL PULMONARY STENOSIS, WITH SPECIAL CONSIDERATION OF THE NATURE OF THE SECONDARY BLOOD CHANGES.[1]

BY F. PARKES WEBER, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE GERMAN HOSPITAL, LONDON;
AND
G. DORNER, M.D. KÖNIGSBERG,
RESIDENT MEDICAL OFFICER TO THE GERMAN HOSPITAL.

IN a previous paper one of us (F. P. W.)[2] described the case of a young man, aged 22 years, with congenital heart disease, great cyanosis, and extreme secondary polycythæmia (polyglobuly)—namely, over 10,000,000 red cells to the cubic millimetre of blood. Evidence was furnished in support of the modern doctrine that the excess in the number of red blood corpuscles in such cases was largely of a compensatory (conservative) nature; that it was a manifestation of the attempt on the part of the bone-marrow to make up for imperfect oxygenation of the blood and tissues of the body by a numerical increase of the red cells—that is to say, of the oxygen carriers of the blood; that it represented, in fact, a vital compensatory reaction analogous to the increase of the polymorphonuclear leucocytes in the blood, consequent on streptococcal invasions, &c. It was furthermore pointed out that the figures obtained by actual blood-counts might make one under-estimate rather than over-estimate the total numerical excess of erythrocytes in the body, for there was considerable evidence indicating that when, in chronic cardiac cases, the erythrocyte-count per cubic millimetre of blood was above the normal (relative polycythæmia) the total volume of blood in the whole body was likewise excessive, a supposition confirmed by the congested appearance of the ears, lips, nose, tongue, and retinæ in many cases.

In the present case we have been able to obtain additional evidence (pointing to the same conclusions) by means of the estimation of the total hæmoglobin and total blood volume in the body by Haldane and Lorrain Smith's carbon

[1] A paper read before the Clinical Section of the Royal Society of Medicine on Jan. 13th, 1911.

[2] F. P. Weber: Edinburgh Medical Journal, 1909, New Series, vol. ii., p. 18.

monoxide method. As concentration of the blood resulting from delayed circulation (stasis) in the capillaries might partly account for the polycythæmia in chronic cardiac cases, we have in the present case attempted to measure (as was proposed in the paper already referred to) the degree of any such blood concentration (if present) by estimating the total solid residue in the patient's blood serum, just as Weintraud and Senator estimated it in cases of so-called "splenomegalic polycythæmia" or "erythræmia."[3]

It has been suggested by Bence, von Koranyi, Mohr, Lommel,[4] and others, and quite recently again by E. C. Seufert,[5] that the excess of red blood corpuscles in cases of splenomegalic polycythæmia (erythræmia) may be accounted for as a compensatory vital reaction on the supposition that the hæmoglobin is defective in quality in such a way as to lower its capacity for taking up oxygen. Similarly it might be suggested that a lowered oxygen capacity of the hæmoglobin is the real cause of polycythæmia, when this is met with in cases of congenital (and acquired) heart disease. There is, however, no evidence that the oxygen capacity of the hæmoglobin is abnormally low or abnormally high in either group of cases, unless Mohr's observation be correct that it was actually diminished in a case of congenital pulmonary stenosis with secondary polycythæmia, which was specially examined in this respect. In cases of polycythæmia with splenomegaly the oxygen capacity of the hæmoglobin has never been found notably reduced. Thus, in two cases of Lommel and one of Mohr it was found to be at the lowest level within normal limits; nor did cases referred to by Senator (1906) and Parkes Weber (two cases in which A. E. Boycott examined the oxygen capacity of the blood) furnish any support to Bence's suggestion.[6] Of great importance are the observations of P. Morawitz and W. Röhmer[7] on the subject. They apparently find that the oxygen capacity of the hæmoglobin does not differ in health or disease from the ordinary standard, even if in some conditions (affecting the salts in the blood) the oxygen is much more readily dissociated from the hæmoglobin than in others. Moreover, we may add that in the rare cases of chronic methæmoglobinæmia and chronic sulph-hæmoglobinæmia (in which less oxygen than normally can be taken up by the red corpuscles) secondary polycythæmia has not been noted.

The patient in the present case is an intelligent young man of Jewish parentage, aged 29 years, a French polisher by trade, who first came under observation on account of temporary bronchitic symptoms. In spite of his congenital heart disease (see later) and the lividity, polycythæmia, &c., connected with it, he has usually enjoyed good health. He has great cyanosis of the lips, tongue, ears, nose, fingers, and toes; the cyanosis varies in degree from time to time and is increased by muscular exercise; it does not seem to be markedly lessened by oxygen inhalation. There is a tendency to epistaxis and there is decided "clubbing" of the fingers and toes. A skiagram of the hands shows the absence of any osteo-arthropathy; the phalangeal bones appear normal. By percussion and Roentgen ray examination the heart is found to be slightly enlarged to the right, the cardiac dulness reaching one finger-breadth to the right of the sternum. There is a rather loud systolic murmur, best heard over the second and third left intercostal spaces, close to the left border of the sternum, doubtless due to pulmonary stenosis. From what has been found in similar cases, it is highly probable that in addition to the pulmonary stenosis there is a considerable defect in the interventricular septum, but of this we have no certain physical signs. Beyond these points there is nothing special to be noted in regard to the examination of the thorax and abdomen. The liver and spleen cannot be felt and are apparently not enlarged. Brachial systolic blood pressure, about 100 mm. Hg. Examination of the urine shows nothing abnormal except that there is intermittent albuminuria of the orthostatic type. The urine passed immediately on getting out of bed in the morning is free from albumin, whereas that passed later yields a more or less thick cloud of albumin; but when microscopically examined it was free from tube-casts. There is no sexual or other form of infantilism. As in cases of "splenomegalic polycythæmia" ("erythræmia") the conjunctivæ tend to be suffused owing to vascular engorgement, and by ophthalmoscopic examination the retinal veins are seen to be distended. In January, 1910, a retinal hæmorrhage at the lower part of the left optic disc was noted.

*Blood examination.*—Red cells (capillary blood). 10,110 000 per cubic millimetre of blood; white cells, 10,275 per cubic millimetre; hæmoglobin, 200 per cent. by Sahli's method, 180 per cent. (on a later occasion) by Haldane's method. The blood is so "thick" that it is relatively difficult to suck it up into a capillary tube; when the fresh blood has been centrifugalised in a cylindrical tube about nine-tenths instead of the normal one-half of the column are taken up by the corpuscular layer. A differential count of 500 white corpuscles (made in September, 1910) gave polymorphonuclear leucocytes 73 per cent., small lymphocytes 19·8 per cent., large lymphocytes 5·2 per cent., transitionals 1·0 per cent., eosinophiles 0·6 per cent., mast-cells 0·4 per cent.; the red corpuscles in the blood-film showed nothing abnormal excepting that three nucleated red corpuscles (normoblasts) were seen during the count of 500 white cells.

The viscosity of the blood as estimated (at 20° C.) by Determann's clinical viscosimeter,[8] was found to be 35·9 times that of water (at 20° C.), that is to say, very greatly in excess of the normal. The coagulability of the blood was less than that of normal blood; the coagulation time, as measured by Sir A. E. Wright's coagulometer, being 15 minutes.[9] The resistance of the blood towards hæmolysis, as tested by the addition of the washed red corpuscles to graduated hypotonic salt solutions, appeared to be rather below the normal standard; very slight hæmolysis was observed when the washed red cells were added to a 0·72 per cent. aqueous solution of sodium chloride, and was complete with a solution of 0·54 per cent.

Specific gravity of the blood (pyknometer method), 1·086; specific gravity of the blood serum (pyknometer method), 1·036; dry residue of the blood, 29·4 per cent.; dry residue of the blood serum (only half a gramme of serum was obtained, which, owing to slight hæmolysis, was coloured red with hæmoglobin), 10·38 per cent.

On Sept. 10th, 1910, Dr. J. S. Haldane and Dr. C. Gordon Douglas kindly estimated the patient's total oxygen capacity (or rather the oxygen capacity of the total hæmoglobin of his blood) and his total blood volume by Haldane and Lorrain Smith's carbon monoxide method.[10] For their investigation and the following report (by Dr. Douglas) we take this opportunity of thanking them. Precautions were taken to guard against a possible source of fallacy (in the method in question) which may arise if insufficient time is allowed for the even distribution of the carbon monoxide through the blood before taking the samples of blood for analysis. The carbon monoxide was given at a slow rate (30½ minutes were occupied by this) by means of the original apparatus employed by Haldane and Lorrain Smith, and the patient was required to breathe for another four minutes into this apparatus. Then he breathed for 17 minutes into a closed respiration apparatus with an effective volume of 15 litres containing pure air, the oxygen in this being kept constant automatically

[3] Vide F. P. Weber: Polycythæmia, Erythrocytosis, and Erythræmia, Quarterly Journal of Medicine, Oxford, 1908, vol. ii., pp. 85–134. By analogy with the terms "leucocytosis" and "leukæmia" the term "erythrocytosis" is sometimes employed to signify a secondary ("reactive") increase of the red blood corpuscles so as to distinguish it from a condition ("erythræmia") in which the increase of the red cells is apparently due to a primary disorder of the erythrocyte-producing tissue of the body.

[4] These authors are quoted by F. P. Weber, Quarterly Journal of Medicine, loc. cit., p. 113.

[5] E. C. Seufert: American Journal of the Medical Sciences, Philadelphia, 1910, vol. cxl., p. 827. Seufert assumes, as causa causans of erythræmia, some deterioration in the quality of the hæmoglobin.

[6] Cases quoted by F. P. Weber, Quarterly Journal of Medicine, loc. cit., p. 114.

[7] P. Morawitz and W. Röhmer: Ueber die Sauerstoffversorgung bei Anämien, Deutsches Archiv für Klinische Medicin, 1908, vol. xciv., pp. 529, et seq.

[8] Determann: Verhandlungen des Kongresses für Innere Medicin, Wiesbaden, 1907, vol. xxiv., p. 533. E. Münzer and F. Bloch, in their work, Experimentelle Beiträge zur Kritik der Viskositätsbestimmungsmethoden (Zeitschrift für Experimentelle Pathologie und Therapie, Berlin, 1910, vol. vii., pp. 174–184), find that Determann's clinical viscosimeter gives too high values. Anyhow, in our present case, the viscosity is, beyond all doubt, excessive.

[9] In cases of erythræmia (splenomegalic polycythæmia) and polycythæmia secondary to cardio-pulmonary affections Parkes Weber has observed that the coagulation of the blood seems to be delayed, as if diminution of coagulability were compensatory (in the modern teleological sense) to great increase of blood-viscosity in these cases (the increased tendency to thrombosis, connected with the excessive blood-viscosity and delayed capillary circulation being to some extent neutralised by the diminution of blood-coagulability).

[10] Haldane and Lorrain Smith: Journal of Physiology, 1900, vol. xxv., p. 331.

by means of an arrangement similar to that devised by Regnault and Reiset. The amount of carbon monoxide lost by the patient into this closed space was sufficiently small to be neglected. During the experiment 239 c.c. of carbon monoxide (measured at 0° C. and 760 mm. Hg pressure) were administered to the patient. Two samples of blood were taken from the finger, one 11½ minutes before the end of the experiment and the other at the end of the experiment. The degree to which the blood was saturated with carbon monoxide—namely, 11·9 per cent.—was the same in the two samples, and there can therefore be little doubt that the time allowed was long enough for the gas to become evenly distributed through the blood. The total carbon monoxide (or oxygen) capacity of the subject (or rather of the hæmoglobin in his blood) was therefore $239/11 \cdot 9 \times 100 = 2010$ c.c. Since the percentage of hæmoglobin by Haldane's hæmoglobinometer was 180, corresponding to an oxygen (or carbon monoxide) capacity of 33·3 per cent., the volume of the patient's blood was $2010/33 \cdot 3 \times 100 = 6040$ c.c. The patient's weight without clothes was 7 st. 4 lb., or 46 kilos, and he had therefore 4·37 c.c. of oxygen capacity (in his hæmoglobin) and 13·13 c.c. of blood per 100 grammes of body weight. Haldane and Lorrain Smith's original results for a series of 14 normal men were 0·98 c.c. of oxygen capacity and 4·78 c.c. of blood per 100 grammes of body weight; Plesch [11] gives 1·12 c.c. of oxygen capacity and 4·78 c.c. of blood, and Oerum [12] gives 5·2 c.c. of blood. It is doubtful (Dr. Douglas writes us) whether the fallacy alluded to above was excluded in all these cases, since more recent observations [13] have shown in three perfectly normal persons an oxygen capacity of about 1·4 c.c. and a blood volume of about 7·5 c.c. per 100 grammes of body weight. In the present case, however, there can be no doubt that both the oxygen capacity and the blood volume per 100 grammes of body weight are very much greater (especially, of course, the former) than those in normal persons, though, on account of the difficulty just mentioned, the values cannot at present be definitely expressed as multiples of normal values.

In regard to these remarks of Dr. Douglas, it may be noted that according to the old idea that the total blood in the whole human body averages about one-thirteenth of the body weight (or 7·7 grammes blood per 100 grammes body weight), the normal weight of the blood in a person of the present patient's body weight (46 kilogrammes) should be about 3538½ grammes.

The present case may be regarded as an extreme example of cyanosis and polycythæmia [14] in an adult secondary to congenital heart disease. It shows that in these cases, as in "splenomegalic polycythæmia" ("erythræmia"), not only the number of red corpuscles and the amount of hæmoglobin per cubic millimetre of blood are greatly above the normal, but so also are the amount of hæmoglobin (as measured by the oxygen capacity) and the volume of blood per 100 grammes of body weight; there is, in fact, a condition of true plethora ("polyhæmia") present, so that the degree of absolute polycythæmia is much greater even than the degree of relative polycythæmia.

The polycythæmia in these cases can therefore only to a very limited extent, if at all, be accounted for by inspissation of the blood owing to blood stasis in the capillaries. But it must, as in "splenomegalic polycythæmia" ("erythræmia"), be almost entirely due to an increased formation of red blood cells in the bone marrow. In the present case the great hæmopoietic activity of the bone marrow is confirmed by the rather large percentage (though it is within normal limits) of the polymorphonuclear leucocytes (73 per cent. of the white cells) and by the presence of a few nucleated red cells in the circulating blood.

That polycythæmia in chronic cardiac cases is not merely "relative polycythæmia"—that, in fact, it is not merely due to concentration of the blood owing to delayed circulation (blood stasis) in the capillaries—has been to some extent shown by the numerical increase of the red cells being found not only in the blood from capillaries and veins, but likewise in that from the arteries. Thus, G. A. Gibson [15] on one occasion, in a boy, aged 16 years, supposed to be suffering from mediastinal pericarditis, found the erythrocytes in the arterial blood to be 7,000,000; in the capillary blood, 8,500,000; and in the blood from a vein, 10,000,000. Palleri and Mergari, [16] in a case of congenital pulmonary stenosis, counted the red cells in capillary blood from the finger at 6,650,000; in venous blood from a vein in the arm at 6,400,000; and in arterial blood from the temporal artery at 5,950,000.

The dry residue of the blood (29·4 per cent.) and of the blood serum (10·38 per cent.) in our present case may be compared with the following data given by W. Bie and W. Maar [17] in their account of a case (a man aged 19 years) of cyanosis and polycythæmia (6,500,000 to over 10,000,000 red cells in the cubic millimetre of blood) secondary to congenital heart disease:—

| | |
|---|---|
| Dry residue of blood (from a vein) ... ... | 25·41 to 25·45 per cent. |
| Dry residue of blood serum ... ... ... | 8·87 to 8·88 ,, |

As approximate values for normal persons the following figures may be given [18]:—

| | |
|---|---|
| Dry residue of blood ... ... ... | 20·3 to 22·8 per cent. |
| Dry residue of blood serum... ... | 9·21 to 10·50 ,, |
| Albumin in blood ... ... ... ... | 22·6 per cent. (von Jaksch). |
| Albumin in blood serum ... ... | 8·8 ,, ,, |
| Specific gravity of blood ... ... | about 1·060 |
| Specific gravity of blood serum... | 1·028 to 1·031. |

The excess of red corpuscles accounts, of course, for the rather large percentage of dry residue and the rather high specific gravity in polycythæmic blood as a whole, but it is with the corresponding figures for the blood serum that we are specially concerned. The fact that these latter are not much, or not at all, above normal limits shows that the blood plasma in polycythæmia secondary to congenital heart disease (as also in "splenomegalic polycythæmia" or "erythræmia") is not greatly if at all concentrated. In other words, it proves that the polycythæmia cannot be accounted for by concentration of the blood as a whole. In our own case, indeed, the figures show that the blood plasma may have been very slightly concentrated, [19] probably as a result of capillary blood stasis. (It may be noted in this connexion that "clubbing" of the fingers and toes was not present in Bie and Maar's case, but was in our case.)

The albumin in the blood and blood serum has not, as far as we know, been estimated in cases of polycythæmia secondary to cardiac disease, but in cases of erythræmia Weintraud and Senator both found the percentage of albumin in the blood serum below the normal, and in an unpublished case of erythræmia G. Dorner estimated it at 7·38 to 7·55 per cent. (that is, below the normal, according to von Jaksch).

Anyhow, we have now decided evidence that the chronic polycythæmia of congenital heart disease is, like that of "erythræmia," associated with excess in the total blood-volume of the body ("plethora vera," "polyhæmia") and with excessive formation of red blood corpuscles in the bone marrow. This is doubtless also true of the polycythæmia sometimes associated with acquired heart disease. Thus Lorrain Smith and H. L. M'Kisack, [20] in the case of a boy, aged 12 years, suffering from adherent pericardium and chronic cyanosis, not only showed that the proportion of red cells to blood plasma was excessive (relative polycythæmia), but also demonstrated by the carbon-monoxide method that

[14] F. Parkes Weber in the Edinburgh Medical Journal (1909, New Series, vol. ii., p. 18) gave references to 14 cases of congenital pulmonary stenosis, or more complicated forms of congenital heart disease, in which blood counts showed that there were over 8,000,000 red cells in the cubic millimetre of blood. In the case he himself described, a man aged 22 years, the red cells were 10,300,000 in the cubic millimetre. In cases of congenital heart disease published since then counts of over 9,000,000 red cells have been recorded by C. A. Fife (Proceedings Philadelphia Pediatric Society, Dec. 14th, 1909; British Journal of Children's Diseases, London, 1910, vol. vii., p. 24), by T. R. Whipham (Proceedings Royal Society of Medicine, 1910, vol. iii., Section for the Study of Disease in Children, p. 149, and Ibid., 1911, vol. iv., p. 3), and by W. Bie and W. Maar (Deutsches Archiv für Klinische Medicin, 1910, vol. xcix., p. 382.)

[19] The blood serum used in our case, as already mentioned, contained a little hæmoglobin.

[20] Lorrain Smith and M'Kisack: Transactions of the Pathological Society of London, 1902, vol. liii., p. 136.

the total volume of blood was far beyond the normal standard, so that there was undoubtedly a condition of true plethora present. It is almost certain that in all chronic cardiac cases, whenever the erythrocyte count per cubic millimetre of blood is above the normal (relative polycythæmia), the total volume of blood in the whole body is likewise excessive. This is indeed what one would expect from the congested appearance in some patients of the face, lips, tongue, and retinæ (as seen by ophthalmoscopic examination) during life, and the hyperæmic condition of their viscera as seen at post-mortem examinations. It is also probable that the total blood volume may be excessive in many chronic cardiac cases even when a blood count shows absence of relative polycythæmia.

E. Weil[21] of Paris was the first to show that the secondary polycythæmia of heart disease is associated with an actual erythroblastic reaction in the bone marrow. In 1901, in post-mortem examinations on two children with congenital stenosis of the pulmonary orifice of the heart and chronic cyanosis, he found that there was red transformation of the bone marrow, microscopic sections of which showed that all traces of the normal fatty tissue had disappeared. His results have been confirmed by Mackey and others. In 1907 L. G. J. Mackey[22] examined microscopic sections made by J. Miller from the bone marrow of a case similar to those of Weil, and obtained similar results to Weil. The polycythæmia of congenital heart disease and chronic cardiac insufficiency is therefore due to great erythroblastic activity of the bone marrow, and represents a true hyperplasia of the erythrocytes and of the erythrocyte-forming tissues of the body, which is, in fact, analogous to the myocardial hypertrophy found in conditions throwing abnormal work on the whole or a portion of the musculature of the heart.

Orthostatic albuminuria seems not to have been observed in most cases of congenital heart disease, but it was very marked in the present patient[23] and in a young man, aged 22 years, whose case was previously described by one of us.[24] We should expect to find it in other cases of congenital heart disease, if accompanied by chronic cyanosis and extreme polycythæmia, and in this connexion, as suggested to us by Dr. A. E. Garrod, the calcium content of the blood might be estimated in similar future cases.

It is worth while drawing attention to the fact that the patient whose case we are now considering takes a good deal of open-air exercise, and, though it may tend temporarily to increase his cyanosis, he declares that he feels much better with exercise than without it. He thinks that an active industrious life suits him better than a lazy one.

The secondary polycythæmia in cases of congenital heart disease is seldom, if ever, rivalled in degree by the secondary polycythæmia which sometimes, as is well known, occurs in chronic acquired valvular affections (of the mitral valve) and in adherent pericardium. It is more nearly rivalled by the marked secondary polycythæmia occasionally associated with late stages of pulmonary emphysema, chronic bronchitis, asthma, old bilateral pleuritic adhesion, chronic interstitial pneumonia, and pulmonary fibrosis. The polycythæmia in all such cases differs from the polycythæmia (possibly of primary myelogenous origin) associated with chronic splenomegaly, which has been termed "erythræmia,"[25] by the not infrequent absence of real cyanosis in erythræmia, especially in its early stages.

What prognostic significance can be attached to the secondary polycythæmia in cardiac cases? In answer to this question we need only repeat what one of us has previously written. Just as hypertrophy of the walls of the heart is useful in so far as it compensates for mechanical defects in the valvular apparatus, so also is polycythæmia useful in so far as it compensates for difficulties in the proper oxygenation of the blood and tissues of the body; but just as in cardiac valvular disease great hypertrophy of the heart indicates some grave defect in the valvular mechanism, so also an extreme increase in the number of erythrocytes in the blood points to there being great impairment of the normal process of oxygenation of the body.

# THE INTRAVENOUS METHOD OF TREATMENT OF SYPHILIS WITH SALVARSAN ("606"), WITH A CONVENIENT APPARATUS FOR SUCH ADMINISTRATION.

BY HUGH WANSEY BAYLY, M.A. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,
PATHOLOGIST TO THE LONDON LOCK HOSPITAL; CLINICAL PATHOLOGIST TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC; ASSISTANT IN THE BACTERIOLOGICAL DEPARTMENT, ST. GEORGE'S HOSPITAL.

Professor Ehrlich now advises that "606," which is on the market under the trade name of "salvarsan," should be administered by the intravenous method and that two doses should be given at an interval of three weeks. For this purpose a syringe has been devised, and as the volume is considerable (250–300 c.c.) the nozzle is provided with two-way taps, so that after one syringeful has been injected the syringe can be refilled without withdrawing the needle from the vein. Anyone, however, with experience of venipuncture will realise that it is difficult to manipulate the taps and the plunger without some slight movement of the needle which may lacerate the vein.

FIG. 2.

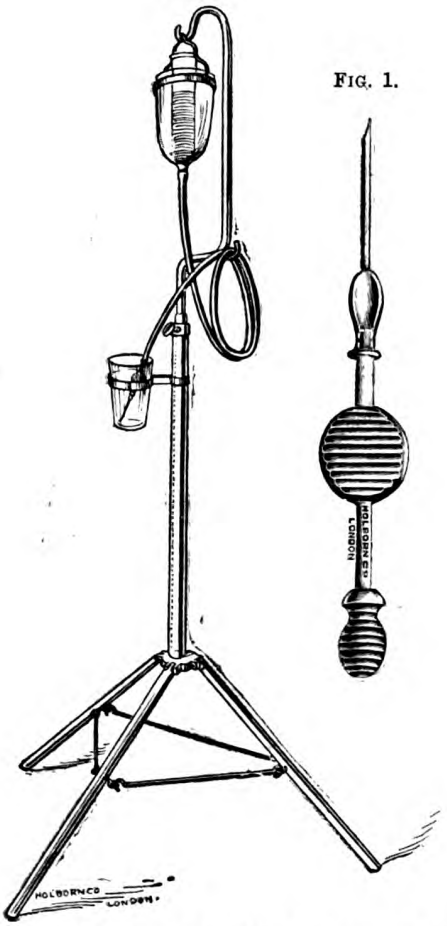

FIG. 1.

In December last, by the kindness and courtesy of Major G. W. Gibbard, R.A.M.C., and Captain L. W. Harrison, R.A.M.C., of the Military Hospital, Rochester-row, I was accorded the privilege of watching the technique there employed for the intravenous administration of "606."[1] I understand that as a matter of routine all suitable cases of syphilis are now treated by "606" given by the venous

[1] West London Medical Journal, January, 1911, p. 46.

route at this hospital. The technique that follows is that used by the officers mentioned, with the exception that I use my own needle-holder, described in THE LANCET of May 1st, 1909, p. 1248, which ensures complete control of the point of the needle (Fig. 1). I have used this holder, which was made for me by Mr. J. H. Montague of 69, New Bond-street, London, W., for over 1500 venipunctures, and find that it greatly facilitates this little operation, especially in cases where the vein is not large or prominent. I have also added a water-jacket to surround the small irrigator containing the "606" solution, as I found that the small volume of solution cooled too rapidly. The Holborn Surgical Instrument Company have also made me a convenient adjustable stand from which to hang the irrigator (Fig. 2). The apparatus consists of a container surrounded by a hot-water jacket, a rubber tube about 4 feet long which connects the container and the needle-holder, and a stout needle 1½ inches long and of the calibre of a fine exploring needle. About 3 inches from the needle-holder a piece of glass tubing is let in to act as a window. The container, tube, and needle-holder are connected up and sterilised before use. The rate of flow is regulated by altering the height of the container, and a clip is applied to the rubber tube about a foot from the needle-holder.

The patient should be in bed, with the arm selected for the infusion supported on a pillow. Having sterilised in the autoclave a glass measure graduated to 300 c.c., and also a glass stirring rod, 30 c.c. of sterilised distilled water is poured into the measure. The end of the phial containing the salvarsan is now broken off, and the contents are *slowly* shaken into the distilled water, which is briskly stirred. A clear yellow acid solution results. This is made up to a volume of 100 c.c. with sterilised normal saline solution (0·9 per cent.). Sterilised normal sodium solution is now added slowly in the proportion of 0·7 c.c. to each 0·1 gramme of salvarsan——viz., 4·2 c.c. of normal sodium hydrate to the solution containing 0·6 gramme of salvarsan. The sodium hydrate should be added till the yellow precipitate which is first produced is just re-dissolved. A slight excess of alkali, however, is of no matter. More normal saline solution is now added to bring the volume up to 300 c.c. All the solutions employed should be at a temperature of about 100° F., and the glass measure is placed in a basin containing water at a temperature of 110°. The water jacket surrounding the irrigator is also filled with water at a temperature of 110°. The irrigator is now filled with warm saline solution which is run through till all air bubbles have been got rid of. The clip is now applied and the needle-holder put into the sterilised tumbler containing some warm sterile saline solution. The skin over the most prominent vein at the bend of the elbow is sterilised by dabbing it with a saturated solution of iodine in chloroform and a bandage applied firmly round the upper arm in order to distend the vein. The needle having been boiled is now adjusted to the holder and a little saline solution run through. The irrigator is now lowered and the needle plunged into the vein and the clip removed. If the needle is in the vein the blood will run into the tube and be seen at the "window." The bandage is now removed and the irrigator raised and the required quantity of the solution of salvarsan is poured in. The solution should only be allowed to run in *slowly* so as to be well diluted by the blood-stream, and it should take about ten minutes to run in all the solution. 0·6 gramme of salvarsan having been diluted up to 300 c.c., 50 c.c. of the diluted fluid contains 0·1 gramme of salvarsan. 0·5 gramme is the usual dose for a healthy male adult and 0·4 gramme for a woman. About 100 c.c. of normal saline solution should be poured into the irrigator when the salvarsan solution has almost run out, so that the needle may be washed free of salvarsan before being withdrawn. Otherwise some salvarsan may escape along the needle track and produce some local inflammation and possibly phlebitis and thrombosis.

The preparation of the patient is of great importance, as if the infusion is given with a full stomach and high blood pressure an alarming condition of feeble rapid pulse and collapse may supervene, which, however, usually passes off when vomiting occurs. Rigors are not uncommon, and may occur from one to two hours after the infusion. The patient sometimes complains of a throbbing in the head and a metallic taste in the mouth and a sense of fulness in the throat. I prepare the patient by giving a pill the night before and a brisk saline purge in the morning of the infusion. I permit only a light breakfast with but little fluid, and allow no food or drink for four hours before the infusion. Since I have adopted these precautions I have recorded no alarming symptoms. The temperature generally becomes raised a few hours after the infusion, and although the rise is usually only a slight one of about a degree, occasionally it reaches 103° or even higher. The temperature usually returns to normal in 24 hours; in one or two cases it has lasted for several days.

There seems to be little doubt that the arsenic is almost entirely eliminated in a week, and therefore there can be little danger in giving a second dose even as early as a fortnight after the first. The patient should be kept in bed for at least three days or for 24 hours after the temperature becomes normal.

The practitioner must be on the look out for phlebitis and thrombosis, although this is a very rare sequela, and if it occurs the arm must be kept absolutely at rest. The Wassermann reaction should be determined before the first infusion and a month after the second infusion.

Upper Berkeley-street, W.

# "NODULAR" FIBROMYOSITIS, AN EVERY-DAY AFFECTION,

## AND ITS IDENTITY WITH SO-CALLED CHRONIC MUSCULAR RHEUMATISM.[1]

BY W. H. MAXWELL TELLING, M.D., B.S. LOND., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE LEEDS GENERAL INFIRMARY AND CLINICAL LECTURER IN MEDICINE TO THE UNIVERSITY OF LEEDS.

IN bringing under notice the affection to which I have given the provisional title of "nodular fibromyositis," I cannot lay claim to any particular originality, for this condition has been recognised and the principles of its efficient treatment laid down for upwards of a hundred years, and descriptions have from time to time appeared in the literature. Dr. Balfour in 1816 wrote a very complete one, and at infrequent intervals other authors made contributions to the subject; one of major importance was by Uno Helleday, a Swede, in 1876. Since then it has been systematically studied on the clinical side, its pathology investigated, and its treatment established beyond doubt by a large number of observers. The Scandinavian school has led the way. In Sweden for the last 35 years the condition has occupied the important and prominent place in medical practice which it deserves, and to this fact the incomparably superior training and efficiency of the Scandinavian school of massage undoubtedly owe their origin. The German school has also furnished many investigators in this subject. The English literature, and I believe also the French, is almost barren of any adequate description. In 1904 Dr. R. Stockman of Glasgow wrote an excellent paper in the *Edinburgh Medical Journal:* to his monograph I am under great obligation. So much for a brief historical survey of what I consider to be the most neglected subject in the English literature of to-day.

Although I am specially concerned to describe a nodular or infiltrated condition of the fibro-muscular tissues and the symptoms to which this may give rise, laying special stress on the more marked and severe cases and on the more unusual examples which not infrequently lead to diagnostic errors, yet over and above this I have a very important thesis to maintain. It is this: That chronic muscular rheumatism, or to quote some of its synonyms—rheumatism, muscular and tendinous rheumatism, myalgia, muscular fibrositis, &c.—is a pathological condition, *the essential morbid process of which is an inflammatory exudation into the fibrous tissues in almost any situation in which fibrous tissue is found.* This exudate leads to swelling and thickening of very variable character and degree: it may be slight and impalpable; severe and definitely tumour-forming; acute and transient; chronic, and eventuating in hard fibrous lumps which resist all efforts at dispersal by the ordinary means at our disposal; but under all circumstances it tends to be painful.

[1] A paper read before the Leeds and West Riding Medico-Chirurgical Society on Nov. 25th, 1910.

To consider, first, the *nature* of the exudate which results in these thickenings, indurations, or actual nodules. The most probable view is that it is a *focal inflammatory hyperplasia of the connective tissue.* This focal hyperplasia is the result either of direct microbic action or, more probably, of toxins conveyed by the blood-stream, and clinical observations abundantly support the view that these results can be brought about by more than one toxic condition. The inflammatory foci may be limited in number, even to a single area, or they may be scattered widely through the fibro-muscular structures of the body. To quote Stockman:—

> The irritant may give rise to proliferation of the fibrous tissue with serous exudation into the inflamed circumscribed parts, which are tender, painful on pressure, and if large can be easily felt or seen in the muscles and fasciæ and on the sternum or other thinly covered bones. At first they may resolve readily enough, leaving no apparent traces behind, but they tend to return on slight provocation, and if much new fibrous tissue forms in the affected area they become permanent and often increase to a considerable size, or spread out over a large area. The older and more fibrous they become the less tendency they have to disappear spontaneously or on treatment. These indurations assume various forms. Sometimes, especially in the lumbar region or in the fascia lata, large portions of the aponeurosis or subcutaneous fibrous tissue become more or less uniformly thickened, with perhaps more prominent indurations at certain points. In severe cases this gives the skin a hard, inelastic, and brawny feel. More commonly the fibrous indurations are more defined and circumscribed, varying in size from a small shot or split pea to an almond, or even half a walnut. The larger ones may be rounded or flattened, the smaller ones often feel like beaded chains along the fibrous edge of a muscle or aponeurosis. Very frequently the thickening takes the form of a strand or cord running through the fascia or subcutaneous fat. Sometimes they are deeply placed in the intermuscular septa, sometimes quite superficially in the subcutaneous tissue, in which case they may adhere to and often slightly pucker the skin. They can often be felt also as small tender projections on the surface of the ribs and other thinly covered bones.

The more recent or more diffuse exudates give rise, when palpated, to a sensation of lumpiness in an affected muscle, or the whole muscle may be brawny to the touch.

First, as to the term we apply to the local thickening; it may be swelling, induration, or infiltration. All these terms have been used, and only in the more advanced cases is use of the term "nodular" justified. "Induration" is perhaps the best general term and has the advantage of not committing one to a particular pathological view, for the view that an inflammatory fibrous hyperplasia is the underlying lesion has not been universally accepted. Moreover, I do not wish to defend very strongly the term "fibro-myositis," because the condition is probably not really a muscular one at all. "Fibrositis" is a better term. "Myositis" is useful, however, because it directs attention to the frequent involvement of the muscles, even though such involvement be secondary, and, again, because it has been largely used in this connexion, as also the terms "myositides" or "myitides," preferred by the Germans.

My position, therefore, may be summarised thus: all chronic rheumatism is essentially an exudative hyperplasia of fibrous tissue, probably inflammatory in origin, and the clinical characters of which depend upon the amount, persistence, and anatomical situation of such inflammatory exudate. It has a preference for certain fibrous areas, the frequency of ordinary lumbago testifying to this. The varying situation of such inflammatory exudate is well illustrated by the fact that most cases of sciatica are due either to pressure on the nerve by a nodule or to infiltration into its sheath. Many cases of supraorbital neuralgia are similarly explained.

The one almost constant symptom which results from this fibrositis is pain. These infiltrations are painful when they are pressed upon, and if vigorously rubbed they swell up and the pain is greatly increased. To quote Stockman once more:—

> Under the action of certain irritants (cold, damp, meteorological changes, muscular exertion, indigestion, and unknown toxins) these indurations are apt to swell and become tenser, and then they give rise to stiffness, aching, or acute pain. The local tension probably exerts pressure on the filaments of sensory nerves; hence these symptoms. Sudden movement of muscles, by increasing the tension or by exerting pressure on the swollen tissue, often greatly aggravates the pain or causes it to shoot excruciatingly.

This local pain on pressure is practically the diagnostic feature of these cases. If a patient presents himself with any of the ordinary manifestations of chronic rheumatism, as a lumbago, sciatica, pleurodynia, or a cephalalgia, and I would add (having abundantly confirmed it from my own experience) with any obscure myalgic or neuralgic pain in any part of the body, a careful investigation should be made of the fibro-muscular tissues of the affected areas. In the more recent diffuse cases there is general tenderness of these tissues, and one may not be able to feel anything which one could definitely assert to be a palpable thickening. But more usually, either with or without such general tenderness, one will find areas which are definitely, often exquisitely, tender to touch. All that is needed is a careful digital exploration of the structures involved, asking the patient to let you know when you are pressing upon a painful spot, though in many cases such a request is far from necessary. It is astonishing how sharply many of the painful areas can be localised, though, of course, this is not always the case.

Having localised the painful areas, the next point is to determine whether they are definitely thickened, either as doughy swellings, strands or septa, or small beads or hard nodules; all variations occur. The detection of indurations is where the sceptics come in, and with a certain measure of justification. The slighter degrees require much practice for their detection, though no one can mistake a really nodular case. Patients sometimes discover their own nodules, and in an extreme case, which I shall presently describe, the patient was the first to draw attention to them as the source of the pain and described them as "glands." But there are two ways of examining a case. To do it properly you must have the patient symmetrically disposed, and the muscles to be explored must be in a state of relaxation. You must carefully and slowly go over the affected areas, using both light and, if necessary, deep pressure (if this can be borne), comparing exactly corresponding areas of the muscles and fibrous tissues on each side of the body. It aids greatly if the skin be smeared with some lubricant, the fingers gliding more easily over the surface. The wrong method is obviously that which means a perfunctory and asymmetrical palpation of the muscles; this prevents one drawing any reliable conclusions.

If the examination is made in the way I have described, after a little practice in detecting the more obscure forms of infiltration one will be surprised at the number of cases yielding positive findings. Two points must not be forgotten. If the exudation is slight, if it is recent, if it is diffuse, or if it is deep-seated and difficult to reach, one cannot expect a positive result. One localises the pain but one cannot convince one's self of the actual thickening. Again, if one finds a painful and thickened area one cannot in most cases swear to it as a thickening without the most careful comparison with the corresponding region on the opposite side, unless, of course, it is particularly well marked and approximately nodular in character.

A few years ago I did not believe in these infiltrations, though their existence was asserted by competent observers. It simply was not in English literature, therefore one disregarded it. But one or two striking cases led me to think that the teaching of other schools might be worthy of investigation. I then began to study a few of the more obvious cases which came in my way. The positive nature of my findings, and the success of treatment based thereon, led me to more and more detailed investigation of these cases, many of which are labelled anything but chronic rheumatism. As a result of the experience which I have now acquired, it is my absolute conviction that this is the real nature of chronic rheumatism, and that all cases form a connected group, whether slight and negative to palpation at the one end of the series, or abounding in nodules of almost gristly hardness at the other. If this be so I think everyone will agree that my sub-title, "an everyday affection," is justified.

Having now, I hope, made the general nature of these cases clear, I can proceed to cite some actual cases, and in doing so I wish to draw attention especially to the following points: (1) the extreme development as to size and hardness of the more severe indurations; (2) the extreme character of the pain that may result from indurations of every kind; and (3) the secondary nervous phenomena, or states of acute or chronic invalidism which may supervene as results of the extreme or persistent pain. It is difficult to realise, short of actual experience, the severity of some of the cases. A further point, and one upon which I wish to lay the greatest possible stress, is the extremely wide range of the painful manifestations, and the serious, yet at the same time avoidable, diagnostic errors for which this is responsible. But really this is strictly deducible from my foregoing description.

I have said that the fibro-muscular apparatus in practically any situation of the body may be affected, in slight or serious degree, in one area or in many. Certain situations are specially favoured. Implication of the tissues of the lumbar

region causes the lumbago familiar to us all, not only in our patients, but more regrettably and not infrequently in our own persons. One nodule is sufficient to cause an extremely painful and persistent lumbago. This is a clinical fact of the greatest importance. The better-known situations of muscular rheumatism I need not enumerate, but some special situations must be mentioned. A very common but much overlooked group of cases is that in which headache is the prominent symptom, the so-called myalgic or indurative headache. This is due to indurations in the retrocollic muscles, which frequently cause a direct or reflex headache, or to indurations in the temporal or other cranial aponeuroses. The abdominal muscles are not infrequently affected; a single nodule in the abdominal area may give rise to either continuous pain or to the most excruciating paroxysms of pain. Such cases have been wrongly diagnosed as gastric ulcer, appendicitis, biliary and renal colic, and a host of other things. Many negative laparotomies undoubtedly owe their undertaking to a failure to recognise chronic rheumatism.

The two points one has to keep in mind are the almost infinite possibilities as to localisation and the variations in the character of the pain owing to the local intensity of the process. In regard to the almost constant symptom of pain I have mainly laid stress up to now upon its local character, occurring with or without pressure, and upon the general stiffness and aching in the affected areas with which you are all familiar, and also with the acute twinges which occur on sudden exertion. But there are two further points which must never be forgotten—the frequency of the radiation of the pain and of its occurrence in paroxysms, such paroxysms being often of the most excruciating and agonising character. These phenomena are probably due to the involvement of nerves and nerve-endings by the indurations, and in really marked and persistent cases a cure is only possible by excision of the offending nodule. As may be expected, pain, from its persistence and its severity, may break down the resisting power of the patient, and many of the so-called chronic neurasthenics owe their myalgic invalidism to this cause. This is no exaggeration. Paroxysmal pain is always liable to be complicated by secondary and reflex phenomena, of which vomiting is a very notable example.

If now this general description be fully comprehended one could almost describe in advance the varieties of case which one would expect to meet. I do not desire to burden this communication with descriptions of many cases or of any at great length, but those which I now quote illustrate very well both the severity and the protean character of the manifestations of this disease. The following is the most severe case that I have so far seen.

CASE 1.—The patient was an unmarried lady, aged 26 years, whom I first saw in consultation with Dr. O. L. Scarborough of Leeds. Very briefly the history is as follows. She was a healthy and vigorous girl when, about four years before the onset of this trouble, she fractured her coccyx, which was removed by Mr. H. Littlewood. She then suffered from severe indigestion and constipation, and some two years later developed suppurative appendicitis, which was successfully operated upon by the same surgeon. Her indigestion was better, but her health was not good; she had much trouble with her teeth, and soon after the operation began to suffer from pain which may be shortly described as a combination of lumbago and sciatica. This increased in severity, being both continuous at times and paroxysmal. Adhesions were suspected, sought for, and not discovered. About 18 months before I saw her she felt in her own back what she described as little lumps or "glands," which were very painful when pressed upon, and from which the pain appeared to take origin. She underwent various treatments—electrical, thermal, and rubbing—at hydropathic establishments and at home, but got worse. Some six months previous to my seeing her the pain began to take on the most severe paroxysmal character. She had crises of pain which were agonising to her, and which, it is no exaggeration to say, were almost torturing to the onlooker. She became practically never free from pain, was bedridden, almost helpless, and a nervous wreck, with, it is not surprising to record, a considerable train of secondary so-called neurotic phenomena. Her resisting power when I saw her was almost *nil*.

Upon examination I found what had, indeed, been found by her medical man, but which he scarcely thought could account for the extreme severity of the pain—numerous and extensive areas of infiltration in the muscles of the lumbar, gluteal, and sciatic regions. There was no doubt about them. If the pain and the patient would have permitted one could have rolled the more superficial ones beneath one's finger. A large sheet of skin over the right gluteus was markedly infiltrated. One induration at the lower border of the gluteal muscle was so massive and so painful that it had been explored with a needle in the hope of reaching some deep-seated suppuration. I immediately put her under a course of special massage, and later gymnastics; and this treatment, commenced on Sept. 9th, 1910, has at the moment of writing resulted in a progressive improvement, so much so that a helpless bedridden invalid, scarcely able to move, suffering the most excruciating pain, is shortly going abroad.

This result has been accomplished in a period of 11 weeks despite many difficulties, such as the elimination of necessary morphia, and the correction of the most marked secondary neuroses. A serious degree of secondary lateral curvature had occurred, and the treatment is still going on, and will have to do for many months yet before a final cure is accomplished, but the change in the patient's condition was nothing short of dramatic.

The next case demonstrates the serious degree of chronic invalidism which may result; the trouble had a different localisation, and I was able to achieve a great deal of benefit from treatment.

CASE 2.—The patient was a widow aged 52 years. She had some general dyspepsia and constipation. She had been a myalgic invalid for about six years when I saw her on Jan. 1st, 1910, but for the last two years had been so bad that she had been unable to earn her living and had been intermittently bedridden, and was in a truly miserable condition. She complained of pain of varying character and intensity in and about the left shoulder, and radiating thence. Her history was very clear, however, about the pain and stiffness always starting in this neighbourhood. She had pain elsewhere, in the lower lumbar region and in the gluteal muscles. The pain was always brought on or aggravated by movement. It occurred in attacks which would last perhaps a fortnight and then leave an interval of some weeks reasonably free from pain. The shoulder muscles—that is, the spinati, the deltoid, &c.—contained numerous infiltrations, easily identifiable as they were almost nodular in character; I could demonstrate them to my students with ease. These were extremely painful to pressure. Massage and exercises at once improved her. In a few weeks she left the hospital a different woman and returned to her work, which she has since satisfactorily performed. I wrote to her this week to come up for re-examination and found that her shoulder pain had not returned. We did not treat the lumbar region and she now has some pain there; on examination there were numerous doughy infiltrations of the erector spinæ muscles; I have no doubt we shall achieve a permanent cure by treating this area as well.

A further example of the generalised nature of this trouble was furnished by the next case:—

CASE 3.—The patient, aged about 30 years, the son of a medical man, had suffered at frequent intervals since childhood from rheumatic pain, principally in the muscles and fibrous tissues of the back; from time to time exacerbations occurred in which he had myalgias almost everywhere. I saw him first about four years ago, and advised treatment by massage, &c. He was due for foreign service, however, and did not carry out this treatment, because on the West Coast of Africa it was difficult to do so, and the pain, though continuous, was not very severe. I saw him on his return three years later, when his general health was much impaired by malaria, &c. He was then becoming a chronic rheumatic, with serious danger of permanent crippling, and faced with the imminent probability of having to give up the service. His lumbar muscles and aponeuroses presented in abundance the usual painful infiltrations. I put the serious aspect of the case very fully before him and pointed out the necessity for a prolonged course of treatment. Being anxious to have my view confirmed in this particular instance I sent him to Dr. Stockman of Glasgow, who fully concurred with the diagnosis and treatment. Under energetic massage and exercises the patient rapidly improved, but before complete cure could be effected (for the case was a very old-standing one) he returned to foreign service. He had, however, learned the routine of the treatment and promised to have it continued for a considerable time. The amount of improvement in this case far exceeded our expectation in the all too short time at our disposal.

The next case is an excellent example of chronic invalidism brought about by a serious and general infiltrative condition of the abdominal muscles, and to a less extent of the muscles of the back.

CASE 4.—The patient, a woman, aged 36 years, was sent to me by Dr. J. W. Hopkins in June, 1909. She was a chronic dyspeptic. She had suffered from an aggravation of the dyspepsia and epigastric pain for nine months before I saw her; her health was considerably impaired and she had lost much weight. Her medical man feared organic disease of the stomach. On examination I found a good deal of general tenderness in the abdominal wall, but could not identify any definite infiltrative areas. As there was no doubt about the dyspeptic symptoms I thought a trial of treatment on this line was indicated. This was strictly carried out, and though the dyspepsia improved, the pain on the whole increased, and her condition became a miserable one. She was sent to me this week again, and then the explanation of things was abundantly clear. Her pain was caused or aggravated by any movement or strain and was relieved by rest; it was not definitely related to food, and was practically continuous, with neuralgic paroxysms from time to time. All the abdominal muscles and fibrous tissues were tender, and there were numerous areas which were exquisitely sensitive to pressure, and any number of infiltrations and irregularities and small pea-sized nodules could be made out.

I quote this case, not because I am yet able to say what treatment can do, but because it is a typical example of the abdominal type of chronic rheumatism, and one which I feel sure will be quite cleared up by massage if that is persevered with for a sufficient length of time.

The next case is an illustration of one single area of fibrositis giving rise to a diagnosis of cardiac disease.

CASE 5.—The patient was an able-bodied policeman, about 26 years of age, sent to me by Dr. G. W. Middlemiss of Settle. Two years before he had had influenza with severe pain, apparently cardiac. This pain persisted up to the time that I saw him. There had been no cardiac lesion noted at any time, and his medical man had persistently refused to diagnose cardiac mischief, though this had been done by another

medical man and he had been told that he was unfit for his duties as a policeman. I found that the pain could be definitely localised to one tender area, involving the upper attachment of the rectus abdominis to the costal cartilages. This was sharply painful, and pressure on it set up the diffuse pain radiating to the cardiac area of which he had complained all through. I showed him how firm massage should be given, and there being but a single area I felt that massage might in this case be performed at home. This was done. Three weeks later I wrote to his doctor and quote his reply. He says: "I have looked up the policeman and he states that he has not felt so well for two years (i.e., since before his first attack of influenza in November, 1908) as he does now. He started the massage as soon as he returned from seeing you, and to this alone he ascribes the great improvement and diminution of pain, for he has neither taken nor done anything else."

Another striking case of localised pain is the following:—

CASE 6.—A medical man, aged 35 years, had suffered for two or three years from attacks of pain in the upper part of the right chest. This would start as a pain localised approximately in the situation of the second right costal cartilage. It would remain localised for some days and would then become more diffuse, spreading over the front of the chest, causing pain, not particularly severe, with every inspiration. This would last for a few days longer and would gradually disappear, the attacks lasting for about 7 to 14 days. Upon examination this pain could be absolutely localised to a tender spot in the upper border of the second right costal cartilage at its junction with the rib, where there was a slight thickening to be made out. Massage of this area quickly caused it to swell up and become exquisitely tender, but a few days' rubbing effected the dispersal of the swelling and a complete cessation of the pain. So far there has been no recurrence.

The next case is a very good example of the mimicry of appendicitis.

CASE 7.—The patient, an anæmic, delicate lad, aged 13 years, for some years had had recurring abdominal pains with sickness, of uncertain origin. About five months ago he had more or less pain in the neighbourhood of the pubic symphysis and sharp pain throughout micturition. There was tenderness in this area and in the right iliac fossa. By X rays the presence of calculus was eliminated with practical certainty, but a dark shadow suggested that there was possibly a calcareous gland in the right iliac fossa, but entire reliance could not be placed on a single observation of this kind. A few days ago I was asked to see him. His medical man said that his general health had greatly improved, but the attacks of pain had been more severe, more definitely localised to the right iliac and pubic regions, where there was great tenderness on pressure, and he feared a chronic appendicitis and the necessity for an operation. The one puzzling feature, however, was that the pain was felt on pressure over the attachment of the rectus to the symphysis, extending well to the left of the middle line. I found on examination that the pain was entirely superficial—that is to say, in the abdominal wall and localised in and near the right iliac fossa. The lower insertion of the rectus abdominis was markedly tender throughout its length. Muscular and fibrous thickenings could be felt, and here and there was a sharply defined pea-sized nodule at a point of maximum tenderness. The condition extended more than half way up the rectus. Deep pressure in the right iliac fossa, of course, also produced pain by dragging on the tendinous structures attached to the symphysis. This case is too recent to be able to report any result of treatment which has been commenced, but I have no doubt but that we shall cure him in a few weeks.[2]

I commend this and the other abdominal cases of fibrositis very specially to the notice of the surgeons, and I think one is permitted to wonder whether some cases of "appendix trouble" that eventuate in operation, and in which the appendix, when removed, presents practically a normal appearance, may not be of this nature.

The following case is a very excellent example of a shoulder type:—

CASE 8.—The patient was a woman, about 40 years of age, who was sent to me by Dr. J. O. Ward of Ferrybridge. For over a year she had had very troublesome pain in the shoulder and down the left arm. It had seemed to take its onset in what was described as an attack of bad neuralgia in the eyes, back of the head and back of the neck, and shoulders, following influenza. This undoubtedly was the acute onset of a more diffuse form of the trouble. The pain subsequently settled down to the muscles about the left shoulder. It came on in attacks in which there were both continuous pain and sharp neuralgic pain down the arm. The persistence and paroxysmal character of this had been so severe as to raise the suggestion of some organic nerve trouble. Upon examination very definite areas of tenderness and infiltration of the muscle in elongated bands and septa could be made out in the deltoid, biceps, and spinatus muscles. Eight days after the commencement of special massage there was a striking improvement. For the first few days the pain was, of course, aggravated, then it was greatly relieved, and she was able to use her arm in a way which had not been possible for months. The case, of course, is still under treatment.[3]

I must content myself with one example out of many of the cephalalgic type of case, which is, I believe, of much more frequent occurrence than is supposed. In this group the indurations occur in the retrocollic muscles, most commonly in the trapezius and sterno-mastoid, and not infrequently in the temporal aponeuroses. They give rise to headache of the most persistent and recurrent character, and unless this condition be remembered in investigating any cases of chronic headache or cephalalgia, I have no hesitation in saying that many of the cases will be missed and the patient's sufferings pass unrelieved.

CASE 9.—The patient was a man, aged 26 years, sent to me by Dr Scarborough. For ten years he had suffered from severe periodic headache which was increasing and rendering him unfit for his duties. No definite cause had been discovered and no treatment had been of any avail. The history was very striking, in that the attacks of headache always started by painful stiffness in the retrocollic muscles. This is a very characteristic feature in these cases and is almost diagnostic. The trapezius muscle contained numerous more or less well-defined infiltrations. A few weeks' massage cured him. Some months afterwards he greeted me in a tramcar with the most effusive thanks, saying that I had transformed his existence by freeing him from pain.

One is sorely tempted to go on quoting cases, each of which presents some different and specially interesting feature; but I have confined myself to my own recent experience, to the exclusion of remarkable cases to be found in the literature.

With regard to the causation of chronic rheumatism, the limits of space will not permit me to go into detail. It is convenient, however, to consider the etiology under two different headings: (1) as to the original causes of the local fibrous thickenings and nodules; and (2) the causes of the attacks of muscular or neuralgic rheumatism when once these indurations are established.

*Original causes.*—By many rheumatism is supposed to be one. That true rheumatism does cause fibrous nodules is familiar to you all, and the remarkable and rapid way in which they disappear is a sufficient answer to those who cavil at the curability of the indurations and nodules of chronic fibrositis. Personally, however, I am unable to accept the view that chronic rheumatism, as ordinarily met with, is a sequel of true original rheumatic fever, or, indeed, that it occurs with any frequency in genuine rheumatic subjects. Influenza is responsible for a certain number of the cases; a fact of clinical importance. Exposure to cold and wet is very frequently responsible. My own feeling is that disturbances of the gastro-intestinal tract, such as oral sepsis, flatulent dyspepsia, chronic constipation, &c., all conditions leading to the production and absorption of toxins, play a somewhat important etiological rôle. Trauma certainly explains some cases, either in the form of frequent slight traumata from over-exertion, as in athletes or labourers, especially when coupled with exposure, or in the form of local injury. This undoubtedly gives rise to the condition, and is a point which is well worth bearing in mind in regard to certain cases occurring under the Workmen's Compensation Act. I quite admit that the majority of the alleged persistent pains and neuralgias which occur in these cases (the painful back and spine being common examples) come very near to deliberate malingering. On the other hand, I am quite certain that some of the cases are genuine examples of the condition we are discussing, and I have been able by suitable treatment to clear up such local pain. An opinion is, perhaps, rather widely held that chronic fibrositic rheumatism is a disease of middle and later life, but this is not so. It is very common in adolescence and in early middle life.

*The exciting causes of pain after the indurations have once formed.*—These are well known to you all and include various meteorological conditions, cold and damp being most prominent. Violent muscular strain is another frequent cause. Acute indigestion, especially resulting from dietetic indiscretions in which champagne and port frequently play a part, is especially liable to precipitate an attack. Many cases also supervene upon an ordinary tonsillitis or pharyngitis, possibly due to septic absorption from this source.

*Treatment.*—Many of the cases are of an acute type, with general malaise and widespread myalgia. These frequently clear up but may settle down into a more chronic condition. There may be a slight degree of temperature. General treatment meted out to a feverish attack, with the employment of the ordinary pain-relieving drugs, is generally sufficient to effect a cure. If the pain is at all localised a single thorough application of massage may result in cure in this early stage.

*The treatment of the chronic cases.—General treatment.*—The removal of any discoverable cause, such as gastro-intestinal irregularities, must be undertaken, and will not only help towards a cure, but will tend to prevent recurrences. During the more acute exacerbations drugs such as sodium salicylate, antipyrin, or pyramidon, and the various means described in the acute attack produce a certain measure of relief, but recurrence is liable to occur indefinitely. To obtain a permanent cure and a complete relief from the recurrent attacks it is absolutely necessary

[2] Since writing the above I am able to report that the pain entirely cleared up in about two weeks' massage, and has so far not returned.

[3] The patient is now perfectly well.

that local treatment should be adopted with a view to obtain a complete dispersal of the indurations.

*Local treatment.*—There are, of course, palliative forms of local treatment. Counter-irritation by blistering or cautery produces relief. Nothing, perhaps, is so efficient as the rubbing in of oil of gaultheria. But these measures are at best temporary; mechanical treatment must be adopted to secure a permanent dispersal. The most important of the forms are massage and systematic exercises. Acupuncture is undoubtedly of great use in relieving the pain, but in my experience does not produce complete dispersal of the infiltrations. Injection of chromic acid into the nodules has its advocates, and is undoubtedly useful, but I think it is a less convenient form of treatment than massage and may be reserved for the more refractory cases. In cases of fibrous nodules which will not yield to simpler measures, and which by implicating or pressing upon nerves cause persistent pain, excision is not only advisable but necessary, the only caution being that the nodule must be very definitely localised beforehand.

*Massage.*—The form of treatment which for over a century has been almost uniformly given first place is some form of massage, and exercises which are designed to replace massage for inaccessible areas and wide tracts and sheets of fibrous tissue. In recent cases from three to ten days will cause dispersal, in more chronic cases weeks or months may be required, and if the indurations have become too fibrous a cure short of excision cannot be expected. There is scarcely any painful ailment of everyday occurrence in which the results of massage are so striking and gratifying as in the more recent cases, while, on the other hand, the cases of years' standing are liable to prove disappointing. This, of course, merely constitutes a plea for the earlier and wider recognition of the disease. Massage should at first be gentle because it causes the painful areas and infiltrations to swell up and to become still more painful and very acutely sensitive to pressure. The patient must always be warned of this, otherwise discouragement will result. In ordinary cases the painful stage is over in a few days, and during this time the patients are often with advantage confined to bed. After that they should get about as much as possible, for exercise is beneficial and tends to improve the condition. This in itself is a striking gain, for with many physicians the routine treatment of these cases is rest. Rest relieves, it is true, because the tender areas are not pulled upon or pressed, but for the most part the disease takes its own time to clear up and not infrequently fails to do so. By active treatment we not only cure but very materially shorten the duration of the disease. Instead of confining your business man with lumbago or sciatica to bed for longer or shorter periods, you can very quickly have him going about his ordinary affairs while at the same time continuing his treatment.

Just a word as to massage. The drawback is its expense, and I know no way of obviating this. Secondly, it is always desirable to employ *skilled* massage, and herein I must digress a little. Some of my patients, on being advised to have massage, inform me that that has already been tried and found to be useless. On inquiry one feels certain the reason why such massage was useless was that the tender areas were left alone because they were tender, and rubbing was directed quite uselessly to those parts which did not require it. In no instance of this kind which has come under my notice has massage failed to be of benefit when given according to my instructions. General massage is useless. The one thing useful is that the tender and infiltrated areas shall be specially marked out for treatment, and the character and vigour of the massage must be varied to suit the requirements of a particular case. I regret to say so, but I have very little confidence in the majority of English-trained masseurs. England at the present moment is flooded with a host of so-called trained rubbers. A large number of these people when calling on one claim to be certificated for massage and medical gymnastics. I daresay they are, but their certificate is obtained on from three to six months', or less, training. Apart from the fact that this results in an almost complete lack of anatomical knowledge, it does not constitute a training. The course in the Swedish school is a full two years' one, and there special attention is devoted to the very numerous class of cases with which we are dealing. To put a case of this kind under a Swedish rubber is to hand it over to an expert. The ordinary English masseurs know practically nothing about this condition (though efficient training *can* be got in England), whereas the Scandinavians not only recognise it, but almost without exception, when cases fall into their hands, treat them at once and successfully without any special directions, and often without any definite diagnosis from the medical man. A correct and nice knowledge of anatomy is of great help in securing the best and most rapid results, and that is just what distinguishes well-trained operators from the rabble of rubbers, comparatively unskilled and anatomically uneducated, which floods our own country.

In conclusion, I would ask practitioners to put the statements that I have made to the test of investigation. Most of us, I am sure, are able to recall difficult cases of persistent neuralgia which baffled elucidation and failed to respond to treatment. To say that such cases were all due to chronic rheumatism would be untrue, but a very large number of them probably were. To treat chronic rheumatism as I have suggested is to get results which are as rapid as they are certain, if the cases be taken early enough, with, naturally, much gratification to the patient. With regard to the infiltrations, which in many cases are slight and elusive, I can only say that their existence is genuine and undoubted, and the advice which one would give, both in regard to them and to cases of chronic rheumatism in general, is "Seek, and ye shall find."

# THE INFLUENCE OF CHLOROFORM WHEN REPEATEDLY ADMINISTERED IN SMALL DOSES.

BY G. HERBERT CLARK, M.B., CH.B. GLASG., D.P.H.,
SENIOR ASSISTANT TO THE PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF GLASGOW.

(*From the Physiological Laboratory, University of Glasgow.*)

THE very striking results obtained when administering a single large dose of chloroform and referred to at length in a paper published in 1908 (1)* suggested to the author that a very much smaller dose might have some influence on the tissues of an animal, particularly when the small dose was repeated daily.

Sir James Crichton-Browne in 1907 (2) called attention to the habit in certain districts of taking lozenges and jujubes containing chloroform, and pointed out that samples of the lozenges contained as much as 2·9 per cent. of chloroform. He pointed out that these lozenges are taken in considerable quantity and over long periods, and he expressed the opinion that such repeated doses must be harmful. The repeated administration of small doses of this drug by the stomach to lower animals is therefore of practical as well as of scientific interest.

In the series of experiments undertaken rabbits were used throughout and the chloroform was administered as in the paper referred to above in one of three different ways—either by inhalation, by the mouth, or subcutaneously. The weight of the animal was taken day by day, and after death in many cases the weight of the heart was taken, and also the weight of the spleen. In all cases portions of liver, spleen, kidney, and heart were examined for fat and also stained and examined for degenerative changes. In the first experiments of the series the animals which were injected with $CHCl_3$ had 0·2 c.c. on two consecutive days, and two days were allowed to elapse before this procedure was repeated. This method proved so rapidly fatal that in the subsequent experiments 0·1 c.c. of $CHCl_3$ was injected daily. In the cases where the rabbits received the $CHCl_3$ in the form of an inhalation they were rapidly anæsthetised and then kept lightly anæsthetised for 15 minutes. In the first experiments of this series this was done daily, but as all the

* The parenthetical figures throughout the paper refer to the bibliography at the end.

animals used died while under the anæsthetic after a very few days the procedure was modified and the anæsthetic given on alternate days. When $CHCl_3$ was given by the stomach it was found that $CHCl_3$ water was easily tolerated by the rabbits and consequently 40 c.c. of this solution were given daily. This contained 0·08 gramme of chloroform. In some cases the rabbits lapped up the fluid without trouble, but in most instances a stomach tube was passed under light ether anæsthesia and the $CHCl_3$ water administered through this. Considering the results of the experiments throughout the series the effect of the $CHCl_3$ administered in the various ways upon the well-being of the animal may be studied by an examination of the weights from day to day. The weights are given in grammes.

| 32 | 2370 | 2270 | 2260 | 2250 | 2300 | 2100 | 2050 | 1950 | 1925 | 1950† |
| 36 | 1600 | 1550 | 1550 | 1550 | 1620 | 1600 | — | — | — | — |

* Survived for one month. Weight at death 1400 grammes.
† Survived for two months. Weight at death 1840 grammes.

Where the administration took place daily the weight fell fairly rapidly. In the case of rabbit No. 7 the weight had fallen nearly 200 grammes in four days. Where the administration was upon alternate days there was in most cases but little change. The daily rise or fall was similar to what was observed in control rabbits. In a few cases, however, a marked fall in weight took place—e.g., rabbits Nos. 22, 30, and 32. The rabbits took food well, and some lived for a long while, having the chloroform administered as described—e.g., No. 22 lived for more than a month and No. 32 for nearly two months.

| 31 | 2450 | 2420 | 2280 | 2250 | 2350 | 2450 | 2300 | 2150 | 2100 | 1950 | 26 days later | 1350 |
| 37 | 1325 | 1300 | 1200 | 1100 | 1200 | 1200 | 1150 | — | — | — | — | — |

In the first three experiments cited above 0·2 c.c. of the anæsthetic was injected on the days signified by italic figures, and it will be noted that the effect of the injections is to lower the weight on the day or days following. This effect is very much more marked in the nine experiments of the second series when the chloroform was given daily until the animal died. Here a considerable fall in weight is shown in some of the animals. In rabbit No. 21 there is a loss of 720 grammes in a month, and in rabbit No. 31 a loss of 1100 grammes in a somewhat shorter time. In many of the animals the loss in weight is very slow at first, but as time progresses it becomes much more rapid. The effect upon weight of administering the chloroform in this way is much more marked than when the drug is administered by inhalation on alternate days, but not so rapidly fatal as where it is given daily in that manner.

TABLE III.—*Administration by the Stomach.*

| No. | Day. | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1st. | 2nd. | 3rd. | 4th. | 5th. | 6th. | 7th. | 8th. | 9th. | 10th. | 11th. | 12th. |

| 15 | 2150 | 2025 | 1975 | 2050 | 2150 | 1950 | 1925 | 1900 | 1940 | 1875 | 1870 | 1870 |
| 18 | 2400 | 2520 | 2500 | 2550 | 2450 | 2300 | 2150 | 4 months later | | | 1350 | |
| 23 | 1700 | 1700 | 1750 | 1700 | 1650 | 1550 | 1500 | 1500 | 1450 | — | 1 mnth later | 1620 |
| 33 | 2100 | 2000 | 2000 | 1900 | 1900 | 1800 | 1700 | 1650 | 1600 | 1550 | 1475 | — |

The amount of $CHCl_3$ given by this method was somewhat smaller than that given in the two previous series, being about 0·08 gramme per diem, but this amount, small as it is (about the same as the $CHCl_3$ content of one lozenge as described by Crichton-Browne (2)), caused a progressive diminution in weight in the animals. In all these cases the diminution in weight was marked, with the exception of No. 14, where a rise in weight was found. The death of the animal was, however, preceded by a very considerable fall. In No. 18 the rabbit tolerated a daily dose for over four months, but it is significant that in that time the animal had lost nearly 50 per cent. of its original weight—or rather more than a kilogramme.

*Histological Changes.*

Concurrently with the alteration in body weight in the animals under experiment histological changes in the organs and tissues examined were found. These changes were for the most part similar to those already described by Bandler (3), Heintz (4), and Ajello (5), and later by Doyon (6) and Billet (7).

*Administration by Inhalation.*

As in the previous series of experiments (1) the kidney and liver suffered considerably when chloroform was administered in this way. The degree of degeneration, however, varied in the different cases, and the difference in degree was not always dependent upon the number of administrations, nor was the change equally marked in the kidney and liver. For example, in the kidney the greatest alteration from the normal was found in animals No. 22, which survived for 31 days, and No. 36, which only survived for six days. The liver in No. 22 was also very badly degenerated, whereas that of No. 36 was not markedly changed. On the other hand, the liver in rabbit No. 30, which lived for five days, showed marked degenerative changes. The cells were coarsely granular and vacuolated; the nuclei took the basic stain badly and fat was abundant. On the whole, it may be stated that the degeneration in the kidney was the most marked feature of administration in this way, and that the kidney was invariably the seat of much change. A point of interest lies in the fact that most of the specimens showed that the glomerular tuft had shrunk away from its capsule—a phenomenon which I showed in a previous contribution was only present after very great changes had taken place in the organ. The liver suffered most in those cases which survived for a considerable time, whereas those animals which succumbed at an early date showed generally a much smaller degree of change. Fat was detected in all instances, the stain used being Scharlach R. The fat was almost always abundant, and generally involved the cells at the centre of the lobule first and extended outwards subsequently.

The spleens of all the animals were examined and the sinuses were invariably found to be engorged with blood. A considerable quantity of an orange-coloured pigment was generally present, and in most instances enormous phagocytes were abundant, the phagocytes being distended with

red corpuscles and often with pigment. The weight of the spleen varied considerably. Four control animals yielded an average weight of 0·78 gramme, each of the animals weighing 2000 grammes or over.

TABLE IV.—*Weight of the Spleen in Animals Anæsthetised.*

| No. | Original weight of animal. | No. of days. | Weight of spleen. |
|---|---|---|---|
| 12 | 1850 grammes. | 20 | 2 grammes. |
| 20 | 2300 ,, | 7 | 0·9 gramme. |
| 22 | 2050 ,, | 31 | 1·2 grammes. |
| 24 | 2250 ,, | 8 | 1·95 ,, |
| 26 | 1600 ,, | 7 | 0·6 gramme. |
| 27 | 1650 ,, | 5 | 1·4 grammes. |
| 30 | 2050 ,, | 5 | 0·72 gramme. |
| 32 | 2370 ,, | 65 | 1·2 grammes. |
| 36 | 1600 ,, | 6 | 1·2 ,, |

The average weight of the animals was 1900 grammes while the average weight of the spleens was 1·24. A large increase of iron, as demonstrated by the relative amount shown by the ferrocyanide HCl stain on the sections, was found in all cases.

In examining the animals after death it was frequently found that the heart muscle appeared flabby and often the walls seemed unusually thin. These organs were therefore fixed and examined for histological changes. The heart muscle stained unequally; some parts appeared quite normal, while other areas showed a granular appearance quite unlike the normal; the transverse striations were lost and the fibres were often segmented. The nuclei in these parts were poorly stained and in some specimens little was left but a mere indication of the position which they occupied. A large number of the cells were vacuolated. This appearance is referred to by Ungar and Junkers (8), and by Heintz (4). The granular and broken-down appearance was very marked in some of the hearts examined, notably in Nos. 12, 20, 22, and 24, but not so marked in No. 32, where the animal survived for 65 days.

It may be noted here that all the animals referred to above died while under the anæsthetic, either while the drug was being administered or within five minutes after stopping the administration.

*Administration by Subcutaneous Injection.*

In the cases of animals Nos. 1, 2, and 3 chloroform was given in doses of 0·2 of a cubic centimetre, and the doses were given irregularly, as shown in Table II. The results in these cases are therefore not strictly comparable with those obtained by daily administration of 0·1 c.c., but they are included here as they illustrate the points to be brought out in this paper.

The animals referred to other than the above received 0·1 c.c. hypodermically each day. The injection appeared to have no immediate effect, and the rabbits so treated were as active after as they were before the administration. Of those which were injected with the larger amount one died after four and two after three administrations, so that the drug was rapidly fatal. Those rabbits which were injected with only 0·1 c.c. lived for longer periods, the average being 11 days. The longest period a rabbit lived during the administration was 30 days and the shortest two days.

The organ which appeared most affected histologically was the liver, and here the changes were comparable with those referred to in a previous paper (1). In one instance, where the rabbit survived for 30 days, the liver was found to be of an orange colour, and contained masses of an orange- or yellow-coloured pigment like that observed in the spleen, and similar to that described by Fraenkel (9), Marthen (10), and Cohn (11). This pigment gave a positive stain for iron. There did not appear to be atrophy. In a few of the livers examined, particularly when taken from animals which had lived for some time, a considerable amount of white fibrous tissue was found between the lobules, as described by Fiessinger (12). The kidneys also generally showed some degree of degenerative change, although in many instances but little alteration from the normal was observed. Congestion and hæmorrhage were generally found, and in the kidneys taken from the animals which were injected with the larger dose of the drug the degeneration in the convoluted as well as the straight tubules was very marked. Frequently the tubules were packed with débris and desquamated epithelium. Where the degeneration was far advanced fat was always found in the degenerated cells. On the whole, however, the kidney appeared to be affected to a somewhat slighter degree in this method of administration.

The spleens showed much the same condition as did those in Table IV. The amount of iron present as shown by the ferrocyanide HCl method of staining was very great, and in No. 19 when the animal was killed after three administrations fully half of the spleen section stained green by this method of staining. The large phagocytes referred to above were also present here in large numbers.

TABLE V.—*The Weights of the Spleens and other Particulars.*

| No. | Original weight of animal. | No. of days. | Weight of spleen. |
|---|---|---|---|
| 16 | 2700 grammes. | 13 | 1·5 grammes. |
| 21 | 3100 ,, | 30 | 1·85 ,, |
| 25 | 1650 ,, | 15 | 0·67 gramme. |
| 28 | 1500 ,, | 3 | 1·2 grammes. |
| 31 | 2450 ,, | 26 | 1·5 ,, |
| 37 | 1325 ,, | 7 | 1·5 ,, |
| Average... | 2121 ,, | 16 | 1·37 ,, |

Thus the average weight of the spleens was 1·37 grammes, as compared with an average weight of 0·78 gramme in the control animals. The hearts generally showed degenerative change, although this was not always marked. Granular cells with loss of the cross-striped appearance were common, and in most cases the nuclei stained irregularly; sometimes the peripheral part of the cardiac muscle appeared to have suffered most, at other times the central parts.

Fat was not observed in any of the hearts examined for it, therein differing from the findings of Fraenkel (9) and supporting Heintz (4).

*Administration by the Stomach.*

The method of administration adopted here was not by any means so rapidly fatal as either of the other methods, contrasting in this with the administration of larger doses in olive oil as detailed in a previous paper, where this was the most fatal method of administration. The average length of life during the administration was 16 days, not taking into account the animal that lived for four and a half months receiving an administration each day. As might also be expected, the liver suffered most of any organ when the chloroform was administered in this way. The amount of degenerative change was great in all cases, but was of a different type in those animals which lived for some time to that in those where death took place in a few days. In those dying soon the cells showed albuminous degeneration, vacuolation, and on two occasions all that could be made out of the liver cells was a kind of network outlining spaces which contained a poorly staining central nucleus surrounded by a small amount of coarsely granular protoplasm. In rabbit No. 18, which lived for more than four months, there was a very great deal of fibrous tissue throughout the liver. Large openings were found irregularly distributed throughout the specimen, and the altered cells showed no sign of definite arrangement.

The greatest degenerative change was observed in No. 33, where the centres of the lobules had lost all trace of their cellular components and were made up of a cheesy mass containing numerous dark granules. Abundance of fat was always found.

The kidneys had on the whole suffered comparatively slightly, although in Nos. 14 and 33 the cells in places were badly degenerated, showing but little sign of the original structure. In No. 33 the glomerular tufts were shrunken, and in a few places in the cortex as well as in the medulla the cells of the tubules were entirely lost. There was rarely congestion and no hæmorrhages were found.

In the spleen the sinuses were found distended with blood, and pigment was present. In Nos. 14, 15, and 23 the amount of iron shown by the ferrocyanide HCl stain was but small, although in 18 and 33 the amount was very great.

The large phagocytes were numerous in those specimens which contained much pigment.

TABLE VI.—*The Weights of the Spleens and other Particulars.*

| No. | Original weight of animal. | No. of days. | Weight of spleen. |
|---|---|---|---|
| 14 | 2300 grammes. | 5 | 1·2 grammes. |
| 15 | 2150 ,, | 14 | 0·3 gramme. |
| 18 | 2400 ,, | 140 | 1·5 grammes. |
| 23 | 1700 ,, | 30 | 0·95 gramme. |
| 33 | 2100 ,, | 11 | 0·8 ,, |

The average weight of the animal was 2130 grammes, while the average weight of the spleens was 0·95 gramme, the latter average being 0·17 gramme above the normal. The hearts showed very little variation from the normal, and the cross striping was seen plainly in all the specimens examined.

*Consideration of Results.*

In reviewing the results of the experiments detailed above, it appears to be proved that given in the form of small doses frequently repeated chloroform is a much more dangerous drug than when given in a single much larger dose. The first doses given appear to lower the vitality of the tissues, so that the later doses have a more marked action.

Idiosyncrasy or a number of undetermined factors appear to influence the action of chloroform on animals, and we find enormous variations between the shortest time and the longest time an animal lived during the administration.

In all the animals examined the liver appeared to have suffered greatly, although, as was to be expected, the most marked degeneration was found where the anæsthetic was given through the stomach. When the drug was inhaled the kidneys seem to have suffered more uniformly than in the other cases, and although the degree of degeneration was not always great, the difference in degree between kidney and liver degeneration was not nearly as marked as when the chloroform was given in either of the other ways.

Very great changes were seen almost uniformly in the spleen even in the animals that died in a few days. The evidence of extensive hæmolysis was most marked. The large-sized phagocytes in many cases distended with dead red corpuscles and in other cases containing a pigment which gave a positive stain for iron, the masses of such pigment apparently lying loose in the spleen, and the large size and weight of the organ all demonstrated its increased activity (Paton and Goodall) (14). The organs in which this increased activity was least manifest were those removed from the rabbits which received the administration through the stomach much diluted with water. Here the average size of the spleen was small and the weights corresponded. The average weight was only 0·17 gramme above the normal, whereas in the other experiments the increase was 0·46 gramme when chloroform was inhaled and 0·59 gramme where it was injected.

When chloroform was inhaled it seemed to have a more marked action on the heart muscle than when it was given through the stomach or injected. Fat was not detected in the hearts examined.

In connexion with the administration by the stomach, it is of interest to note that the amount of chloroform given in each administration was comparable with the quantity described by Sir James Crichton-Browne (2) as being present in one linseed, liquorice, and chlorodyne lozenge. The average weight of a full-grown rabbit is about 2 kilogrammes, while 70 kilogrammes represents the weight of a full-grown man. Thus 30 to 40 of these lozenges per diem in a man gives the same proportion of chloroform to body weight as in the experiments, and correspondingly less in a woman or a child. Many rabbits are very susceptible to the action of chloroform, but even in the one example where the animal lived for a long while the liver changes were of a very striking description. The lesions found in rabbits closely resemble those reported in fatal human cases of chloroform poisoning by Stiles and McDonald (15) and others.

The mortality among rabbits which have been anæsthetised through the respiratory passages and the changes in heart, liver, and kidney found after death emphasise the danger of repeated administration by this method, even when the anæsthetic is only exhibited for very short periods.

*Summary.*

1. Chloroform repeatedly administered by the respiratory passages, subcutaneously, and by the stomach in small doses rapidly kills rabbits.

2. The liver shows degeneration of the cells sometimes so marked that the whole centre of the lobule is broken down into débris. The cells in the centre of the lobule are early affected, those further out later. Fat is always present, generally in large quantities.

3. The kidney suffers to some extent, but relatively more when the chloroform is inhaled than when injected or given by the stomach. Fat is occasionally found in degenerated cells.

4. The spleen shows intense congestion, the sinuses being packed with red blood corpuscles. Along with the red corpuscles an orange-coloured pigment is generally present which reacts to the stain for iron. A large number of very large phagocytes are present in most cases. The average weight of the spleen was 0·46 gramme heavier than the controls when chloroform was inhaled, and 0·59 gramme and 0·17 gramme heavier when injected and when given by the stomach respectively.

5. Degenerative changes were observed in the cardiac muscle. Fat was not observed in any of hearts examined.

(A grant was received from the Carnegie Trust to defray the expenses of this research.)

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### A CASE OF NERVE DEAFNESS IN A SYPHILITIC OF THIRTY YEARS' STANDING.

BY ARTHUR H. CHEATLE, F.R.C.S. ENG.,
AURAL SURGEON, KING'S COLLEGE HOSPITAL.

A MAN, aged 51 years, complained of deafness in both ears, the right being the worse, and "ringing" tinnitus. The trouble had begun insidiously seven or eight years previously and seemed to have become stationary. Any noise around him made him feel deafer. He had not suffered with giddiness, headache, herpes, or facial paralysis, and there was no history of anything to cause deafness with the exception of syphilis at the age of 21 years. According to the history, consistent treatment of the syphilis had only lasted six months. There had not been any tertiary lesion and there had not been any girdle or lightning pains.

On examination, there was nothing abnormal in the membranes, nose, nasopharynx, or pharynx. The conversational voice could be heard at 2 inches on the right side and six inches on the left. The forced whisper was not heard on the right side and only at the meatus on the left. The tuning-fork tests clearly demonstrated internal ear deafness. The Eustachian tubes were quite clear on catheterisation, which made the ears feel decidedly "stuffy." The pupils were not contracted and were equal and reacted to light. There was no nystagmus. The knee-jerks were brisk. There was no incoördination, disturbance of equilibration, or loss of sensation, and no evidence of any other nerve implication. Dr. W. d'Este Emery reported that the blood gave a powerful Wassermann reaction.

In opening a discussion on "Syphilis in Relation to Otology" at the Otological Section of the Royal Society of

Medicine in November last, I had stated that "I cannot be certain that, apart from tabes, there is a progressive sclerosis of the auditory nerve alone," but this case appears to me to be of that nature and is probably a type which will not infrequently be met with. Cases of progressive internal ear deafness and tinnitus with a slow and insidious onset occurring without any assignable cause are strongly suspicious and demand the Wassermann test. I am as yet unable to say what effect antisyphilitic treatment will have.

Savile-row, W.

## A CASE OF ACONITE POISONING.

BY T. INGLIS, F.R.C.P. EDIN.

THE patient, a married woman, aged 45 years, a multipara, had suffered from rheumatism, shortness of breath, and swelled feet. She was at the beginning of the menopause and had had two or three floodings. Lately she had been upset by family and money matters which brought on neuralgia and aggravated gloomy thoughts of impending evil. To save money she went to a London hospital, where she was supplied with a mixture and liniment. The latter was in an ordinary clear medicine bottle, but marked "The Liniment" on a red poison label. Next morning, not feeling well, she carelessly drank by mistake about three ounces of the liniment, not noticing the label, it being turned towards the wall. At once she recognised that a mistake had been made from the taste of camphor (most officinal liniments contain it), followed by a hot tingling feeling in the mouth, then numbness. A sick giddiness crept over her, with gastric pains, and she collapsed on the floor, where she was found two hours later by her husband. He sent to a druggist for ipecacuanha wine, and administered a strong emetic. But by this time most of the poison had been absorbed and very little of it was returned. Feelings of sickness continued and a violent attack of clonic convulsions supervened. There was a delay in getting the medical man, who found the patient lying on the floor speechless, cold, pale, skin moist, pulseless, respiration very faint and irregular, and the pupils dilated and insensitive. The temperature was 96·6° F. There was no ptosis. At intervals she was able to gasp out that there was terrible gastric and abdominal pain and that all the body was alive with irritation and pricking of the skin, succeeded by numbness. The latter fact, together with the pallor and damp skin, pointed to aconite poisoning to the exclusion of belladonna. Three times after attacks of clonic convulsions she appeared to be dead, but when they ceased the mind was clear and unaffected. As ipecacuanha (a cardiac depressant) had been given, it was thought advisable only to give one mustard emetic to save the enfeebled heart. The head was kept low, the feet were raised, a sinapism was placed over the heart, and hot bottles and flannels were applied to the lower extremities and abdomen. Strychnine and digitalis were given hypodermically and brandy was injected per rectum. Artificial respiration was unceasingly kept up. After an anxious six hours the breathing became stronger, an irregular intermitting pulse could be felt at the wrist, whilst the body warmth slowly returned. A little coffee and brandy were swallowed and retained. So the crisis passed. There was no purging at any time, but subsequent actions of the bowel were hard and gritty, possibly from particles of the powdered aconite root. The quantity of aconite taken may be roughly estimated as sufficient to kill six persons.

Yokohama.

LECTURES ON MILK.—A course of six lectures on Milk, followed by practical work, will be delivered by Dr. A. Harden, F.R.S., on Thursday evenings, at 7.30 o'clock, at the South-Western Polytechnic Institute, Manresa-road, Chelsea, S.W., commencing on Feb. 2nd. The following subjects will be dealt with: (1) The Chief Properties of Milk; (2) Bacteria in Milk; (3) Changes Produced in Milk by Bacteria; (4) Spread of Disease by Milk; and (5) Preventive Measures. A practical class will be held immediately after the lecture, the work of which will include simple methods of ascertaining the composition of milk and the detection of impurities and preservatives in milk.

## ROYAL SOCIETY OF MEDICINE.

### CLINICAL SECTION.

*Exhibition of Cases.*

A MEETING of this section was held on Jan. 13th, Mr. W. BRUCE CLARKE being in the chair.

Dr. J. D. ROLLESTON and Dr. N. S. MACNAUGHTAN showed three cases of Familial Pigmentary Dermo-fibromatosis. The first patient was the father of the two other cases. He was aged 47 years. He had not suffered from any illnesses beyond scarlet fever and measles in early childhood; his general health was good, apart from "bilious attacks" about once a month. He had had the nodules and pigmentation as long as he could remember; he did not know which appeared first. Nodules had become more numerous since a severe attack of pneumonia 13 years ago. Both parents were alive; his father, aged 72 years, showed numerous small nævi and moles on the trunk; his mother, aged 73 years, had some nævi on the trunk and a large area of pigmentation in the lumbo-sacral region; both showed slight yellowish tinge of skin. The trunk of the patient was thickly set with molluscous tumours, mostly sessile, in all stages of development. There were a few lesions on the face and limbs. The skin of the abdomen and inner side of the thighs showed yellow groundwork of pigmentation, with pigmented spots and a few *café-au-lait* patches. The pigmentation of the anterior axillary folds was well marked. There was no pigmentation of the buccal mucosa and no deformities of the skeleton nor mental symptoms. The knee- and ankle-jerks were active. The plantar reflex was flexor. The blood count was normal, and the blood pressure was 130 mm. Hg. The second case was a daughter of the first patient and was aged 13 years. There was a general yellowish tinge of the skin and punctiform pigment spots and *café-au-lait* patches were scattered over the neck, the trunk, the arms, and the thighs; there was one ink-spot over the left costal margin and there were numerous blue spots, some slightly raised above the skin, on the trunk and the thighs, one being on the left upper arm. There was a nævoid growth of the right half of the upper lip, displacing upwards the ala nasi; the skin over it had a bluish tinge and was covered with fine hairs. The corresponding alveolus had a prominent bony ridge. There was a small nodule in the left frontal region at the margin of the hairy scalp. Slight scoliosis was present and the intelligence was good. She suffered from "bilious attacks" about every two months. A mild attack of diphtheria occurred in November and December, 1910; since the commencement of the attack blue spots had become more numerous. Blood examination showed slight anæmia. The third case was another daughter, aged 5 years. There was a general yellowish tinge of skin, punctiform pigment spots, and *café-au-lait* patches on the neck and trunk; the limbs were free; no molluscum was present. Diphtheria occurred in November and December, 1910; the mother thought that the patches had become more numerous since the beginning of the attack. The other two children, both boys, aged 14 and 10 years respectively, showed slight yellowish tinge of the skin but no molluscum or pigmentation. The eldest boy had one small mole on the chest and another on the left buttock. Microscopical examination of one of the father's tumours and of the eldest daughter's blue spots showed presence of fibrous tissue but no nerve fibres. Dr. Rolleston said that he and Dr. MacNaughtan had applied the term invented by Professor Chauffard of "pigmentary dermo-fibromatosis" to the condition illustrated by that family in preference to neuro-fibromatosis for three reasons: (1) The lesions appeared to be independent of the cutaneous nerves; (2) there were no nodular swellings on the deeper nerves; (3) histological examination of sections in the cases of the father and eldest child showed an absence of nerve fibres. The condition was undoubtedly closely related to von Recklinghausen's disease, of which it might be regarded as an incomplete form, or *forme fruste*. In the case of the two girls they had an excellent example of the disease developing in different stages. In the elder girl the pigment patches preceded the blue spots—i.e., the small

molluscous tumours. In the younger girl no molluscous tumours had at present appeared, but it was highly probable that they would develop later. Of special interest in the three cases was the relation of the condition to acute infections. The father stated that after an attack of pneumonia 13 years ago the molluscous tumours became more numerous, and during the stay of the two children in hospital for diphtheria the molluscous tumours in the case of the elder girl and the pigment spots in the younger girl increased in number and size. Probably the approach of puberty superadded to the recent infection would cause a further development of the lesions in the older girl. They would like to draw attention to the familial occurrence of so-called "bilious attacks." The occurrence of gastric disturbance had been noted in several cases of von Recklinghausen's disease, in some cases being associated with neuro-fibromata of the gastric wall. It was noteworthy that familial vomiting occurred in an incomplete series of cases of von Recklinghausen's disease reported by Dr. Parkes Weber. In view of the fact that attempts had been made to associate von Recklinghausen's disease with tuberculosis, they had found no evidence of tuberculosis either in the father or the children. Von Pirquet's reaction in the case of the children was negative. The doctrine of pluriglandular insufficiency was also inapplicable in their cases, as there were no mental or physical signs of disturbance of the glands of internal secretion. In conclusion, Dr. Rolleston stated that the blood examination made by Dr. MacNaughtan showed that the percentage of eosinophiles was normal, which in some cases of von Recklinghausen's disease had risen to 15 or 21 per cent.—Dr. H. D. ROLLESTON considered that the growth on the right half of the upper lip of the daughter aged 13 years was probably a plexiform neuroma, and Dr. F. PARKES WEBER thought also that it was a variety of that condition.—Dr. F. J. POYNTON described a case of Recklinghausen's disease in which excruciating pain was experienced, and asked if the cases shown were likely to develop painful tumours.—Dr. G. A. SUTHERLAND said that growths similar to that on the lip of the girl aged 13 years often occurred on the upper eyelid.—Dr. J. GALLOWAY described two cases in which surgical interference was tried for growth like that on the girl's lip—in the first success was not obtained and in the second no great result was achieved, but Mr. A. CARLESS narrated a case of similar growth on the chest which was successfully dealt with surgically.

Mr. C. C. CHOYCE showed two cases. The first was one of Symmetrical Gangrene of both legs, fingers of both hands, and nose. The patient, a marine coal-trimmer, aged 25 years, was a coloured native of Grenada, and had never before left the West Indies. He had never had any previous illness except gonorrhœa. No evidence could be obtained of past syphilis, Raynaud's phenomenon, or renal disease. Whilst in the Channel, on his first sea voyage, on a day that was not unusually cold, he suddenly noticed on coming on deck that his fingers and feet became very cold. He lost sensation in them, and then power of movement, and noticed that warming before the fire did not restore warmth and sensation. During that night his right foot was painful and became swollen, but he was able to do some of his work during the next day. During the next night his left foot also became swollen and painful; his fingers remained cold and numb, but were not painful. During these two days he passed black urine; since then it had been quite clear. There were no rigors, no lumbar pain, no vomiting, no diarrhœa, and no soreness of the gums or tongue. For some ten days he was invalided on his ship, suffering from thirst, acute pains in the legs and arms, and hyperæsthesia above the levels of anæsthesia. On arrival in the Thames he was sent into the Seamen's Hospital, Albert Dock. On admission his temperature was 101° F., but his general condition was fair. There was no evidence of a general endarteritis; there was no rash. The mouth was normal, except for dry sordes about the lips and a moist, slight fur on the tongue. The feet from the toes to 1½ inches above the ankles were glossy, black, swollen, and quite cold. There was no definite pitting on pressure; no pulsation could be made out. Deep pressure could be felt by the patient, but all sense of ordinary touch was lost, except at a ring, half an inch wide, at the upper limit of the gangrene, where there was marked hyperæsthesia. The patient could move the toes and ankles. The knee-jerks were present and normal. There was slight pain on deep pressure in the calves, but otherwise sensation above was normal. The fingers on both hands had the outer three fingers black and cold, with a ring of marked hyperæsthesia at the line of the metacarpo-phalangeal joints. The index fingers both showed black, cold, anæsthetic patches. The patient could move the fingers, although the terminal phalanges of the outer three fingers of each hand were dry and shrivelled. The nose showed at its tip a small gangrenous patch of about the size of a threepenny-piece. The ears were normal. The urine contained no albumin, blood, or sugar; its specific gravity was 1025. The stools were natural. The red blood corpuscles were 3,900,000 per cubic millimetre; the white blood corpuscles, 25,000 per cubic millimetre; and the hæmoglobin 70 per cent. Differential count: lymphocytes, 9 per cent.; large mononuclears, 5 per cent.; polymorphonuclears, 86 per cent. The limbs were thoroughly cleansed with acetone and treated aseptically. A well-marked ulcerating line of separation had formed 2 inches above each ankle. Both superficial and deep tissues appeared entirely dead. There had been some suppuration of the left leg, but the patient's general condition had steadily improved.

Mr. CHOYCE'S second case was one of Actinomycosis of the Abdominal Wall. The patient was a man, aged 49 years, upon whom he operated for appendicitic abscess in June of last year. The abscess was a thick-walled bilocular one which contained a concretion and about one pint of fæcal-smelling pus. The appendix was not readily found; the abscess was therefore drained and the appendix left for a future operation. The patient rapidly improved in health, and his wound healing well he left hospital in July, but stated that almost immediately after leaving the hospital he noticed some firm swelling in the region of the upper part of the left inguinal canal. That was slightly tender, but his general health was good. Nothing abnormal could be felt on the left side of the abdomen at the time of operation. The swelling on the left side of the abdomen gradually enlarged until, when seen again in September it extended from the left iliac spine to within 1 inch of the middle line, and from Poupart's ligament to within 3 inches of the costal margin above. It seemed to be confined to the abdominal wall, but was not moveable apart from the ilium. The abdomen moved freely on respiration. The tumour was tender on deep pressure, but was not painful. His temperature was normal, and the general health not markedly affected. A leucocyte count showed the presence of 10,000 per cubic millimetre. There was a history of syphilis ten years before. The patient was treated with large doses of potassium iodide. A fortnight later the tumour was larger, being more prominent anteriorly, and now extending up to within 1½ inches of the costal margin and to within ½ inch of the middle line. There was a reddened, slightly œdematous, area over the centre, the temperature was 101° F., and the leucocyte count now 20,000. An incision was made into the softened area, and an abscess cavity found containing a few drachms of pus and surrounded by dense masses of fibrous tissue. No actinomyces nor other organisms were found at this time. The abscess readily healed and the upper part of the mass diminished in size, but there remained a fibrous mass extending down behind the pubes. The temperature again became normal after the operation. At the beginning of November, as the tumour was increasing in size again, the old scar was excised with a small portion of the mass. In that were found a few fistulous tracks lined with granulations, and containing a slimy discharge in which were to be seen a few yellow granules. Those on examination proved to be composed of actinomyces. The incision carried through the mass showed that the peritoneum was free. The tumour was composed of fibrous tissue and a small round-celled infiltration. Since that date, under treatment of large doses of potassium iodide, the tumour had been decreasing in size, especially in its upper parts. It had, however, spread across to the right side of the abdomen. Now that part, too, was decreasing slowly.

Dr. GALLOWAY showed a case of Pulmonary Stenosis (Congenital)? The patient was a girl, aged 4½ years, who was sent to hospital on the discovery of abnormality of the heart. She had "bronchitis or pneumonia" when 4 months old; the medical man who attended her said that she had heart disease, which was probably congenital. She was

a fairly developed child and gave evidence of no serious defect on inspection. There was no cyanosis nor clubbing of the fingers, but she became breathless while at play, and perhaps a little cyanosed. There was a well-marked long-continued systolic murmur to be heard, its point of greatest intensity being at the base of the heart to the left of the sternum. The case was shown as one of congenital pulmonary stenosis or of patent ductus arteriosus.

Mr. SIDNEY A. BOYD showed a case of Hæmangioma of the Foot.

Dr. PARKES WEBER read a paper on a case of Congenital Pulmonary Stenosis, with special consideration of the nature of the secondary blood changes, which is published in full in this issue of THE LANCET, p. 150.

## SOCIETY OF MEDICAL OFFICERS OF HEALTH.

*The Relation of Public Health to Industrial Diseases.*

A MEETING of this society was held on Jan. 13th, Dr. W. G. WILLOUGHBY, the President, being in the chair.

In the unavoidable absence of Dr. B. A. Whitelegge, a discussion upon the Relation of Public Health to Industrial Diseases was introduced by

Mr. W. F. DEARDEN, who said that the excessive mortality from certain diseases which afflicted workpeople engaged in particular industrial pursuits must point to the existence of some method of causation common to each industry concerned, whether or not this be directly or indirectly attributable to the trade process itself. There was one outside factor, however—viz., alcoholism—which appeared to pick out certain trades in the exercise of its deleterious effects. Workers subjected to excessive heat, as in glass-works and rubber-works, were, on account of the thirst created, very addicted to the use of alcohol and suffered accordingly. The alcoholic tendency of printers, hatters, and shoemakers was well known; waterproof-cloth spreaders, who were subjected to naphtha fumes, were very rapidly affected by alcohol, and it was suicidal for workers in lead to indulge in the habit. The direct influence of trade processes upon the production of disease was particularly marked in dusty occupations, and could be further illustrated by a reference to the dangerous trade processes scheduled in the Workmen's Compensation Act. One way in which industry affected public health was the production of a special liability to incapacity and death as the result of accident. In 1909 there were 39,966 accidents investigated by certifying factory surgeons, and of these 946 were fatal. The provisions of the Factory Act referring to safety came quite within the range of public health, including as they did the providing of means for escape from fire and the fencing of dangerous machinery. General sanitary requirements had reference to cleanliness, proper provision of closet accommodation, air-space, ventilation, temperature, and the drainage of floors where wet processes were carried on, though it appeared strange that there were no obligations as to efficient lighting. The investigations by certifying surgeons of cases of anthrax, plumbism, mercury, phosphorus, or arsenic poisoning contracted in a factory or workshop were of great value, and had resulted in a supply of information which had been of immense service in demonstrating the necessity for supervision of the processes. Although much had been done to improve the lot of the workers since the first Factory Act was passed over a hundred years ago, the factory sanitarian could not yet rest on his oars. On the other hand, the medical officer of health must recognise the influence on the general health of the community of the ill-effects which kept pace with, and which could not be dissociated from, industrial occupations.

Dr. EDWARD C. SEATON referred to the work of Dr. Whitelegge at the Home Office, and Dr. G. P. BATE considered that one of the most important reforms of recent years was the introduction of the conditional certificate of employment for children. Many children in an indifferent state of health were better if working at a suitable employment than running wild in the street. He pointed to the greater efficiency of inspectors of factories, who were now obliged to have a working knowledge of hygienic conditions.

Dr. A. GLEN PARK also spoke with approval of the conditional certificates, but regretted that he was not empowered as a certifying surgeon to make a subsequent examination of a child for the purpose of ascertaining whether conditions he had laid down, such as the provision of spectacles, had been carried out. There was no doubt that these certificates had encouraged certifying surgeons to allot suitable work to particular children.

Dr. ALFRED GREENWOOD would like to see a closer coöperation between medical officers of health and certifying surgeons, and suggested that the latter should have access to the results of the medical inspections of school children.

Mr. F. E. FREMANTLE advocated courses of popular instruction for workmen in the methods to be employed in preventing accidents, and suggested that models of machinery properly guarded should be placed in public museums.

Dr. J. H. KEAY supported this suggestion, and referred to the fact that children who had been examined by a school medical officer upon leaving school were frequently rejected by the certifying surgeon on account of defective eyesight.

Dr. E. L. COLLIS urged the importance of medical officers of health taking more interest in conditions of employment in special diseases, and referred with satisfaction to the work in this direction which had been done by Dr. Greenwood and Dr. H. Scurfield. He emphasised the necessity for investigating the invalidity of special industries and considered that danger in occupation was indicated more by invalidity than by mortality.

Mr. HERBERT JONES, Dr. A. H. BYGOTT, Dr. SIDNEY DAVIES, Dr. W. BUTLER, and the PRESIDENT also took part in the discussion.

## SOCIETY FOR THE STUDY OF INEBRIETY.

*The Influence of Parental Alcoholism on the Physique and Ability of Offspring.*

THE discussion on this subject, which was held at the winter meeting of this society on Jan. 10th in the rooms of the Medical Society of London, was opened by Dr. T. B. HYSLOP, the President, in an address which we published last week. Dr. Hyslop, it will be seen, emphasised the fact that recent study of the question had greatly increased the sense of its complexity, allowing that he personally under advancing experience was more hesitant than formerly in connecting the mental defects and disorders noted in the offspring with the alcoholism of the parents. The real question to be answered, he said, was, Does parental alcoholism (of a pernicious kind)—apart from parental degeneracy, which, together with a tendency to alcoholism, is hereditable—influence the physique and ability of offspring at any age? He finished his address by saying that the conclusions arrived at by the Galton Laboratory School of Eugenics and their critics dealt with part only of the general question at issue, adding, "When further investigations shall have demonstrated the influence of parental alcoholism on parental degeneracy, and the combined influence on the physique and ability of offspring, we shall be better able to speak with authority for the guidance of the community."

Mrs. SCHARLIEB expressed her general concurrence with Dr. Hyslop's views, and urged the necessity of keeping an open mind on this question pending the result of fuller inquiry.

Sir VICTOR HORSLEY regretted that no representative of the Eugenics Laboratory had thought fit to attend the meeting, in view of Professor Karl Pearson's recent incursion into this question. He referred to the damaging criticisms to which Professor Pearson's figures had been subjected by the Cambridge economists, and mentioned that as the result of a careful scrutiny of the Edinburgh Charity Organisation Society's report, utilised in the Eugenics Laboratory inquiry, he hoped in a few days to draw public attention to other grave inaccuracies in Professor Pearson's statements.[1] He emphasised the fact that in the biometric data no evidence at all was offered to prove the alcoholism of the so-called alcoholic parents.

Dr. C. W. SALEEBY pointed out that Professor Pearson himself stated at the outset of his paper that there was a difference in the quality of the stock in the sober and in the drinking parents investigated, and remarked that this fact must vitiate any conclusion as to differences in the quality of the offspring. To test the effect of alcoholism the comparison

[1] See Brit. Med. Jour., Jan. 14th, p. 112.

should be between like stocks. He referred to Forel's views on blastophthoria, and suggested that there was ground for distinguishing an acute variety of this condition, as in cases where defect was supposed to depend on conception during drunkenness, and a chronic variety as in ordinary cases of chronic alcoholism. He indicated the parallel instances of degeneracy induced by such poisons as lead and arsenic. The further evidence needed with reference to the whole problem would be best supplied by experiments on the lower animals.

Dr. W. C. SULLIVAN remarked that in the really scientific literature of the subject the alcoholism which was asserted to act injuriously on the offspring was chronic alcoholism, and the belief in its detrimental action rested on medical observations in which it was definitely ascertained that this chronic intoxication really existed in the parent, and, further, that it existed before the conception of the child. Neither of these conditions was satisfied in the biometric data, where parents were described as alcoholic on no better evidence than the fact that social workers thought that "they were drinking more than was good for them or their homes." If the biometricians really believed that these alcoholic parents were suffering from chronic alcoholism, then they were asserting that three-fifths of the adult male population of Edinburgh, as shown by their random sample, were chronic alcoholics—a figure absurd on the face of it. The latest study of the biometricians on this question showed their want of first-hand acquaintance with the facts of alcoholism. Otherwise they would never have imagined that the inmates of inebriate reformatories were cases of "extreme alcoholism" or that the "intensity of their alcoholism" could be measured by the number of their convictions. This was due to the common illusion that drunkenness was the sole cause and true measure of alcoholism, whereas in fact the most alcoholic individuals amongst police-court cases, from which the so-called inebriates were drawn, were precisely those who had fewest convictions.

Dr. E. CLAUDE TAYLOR entered a protest against the suggestion in the biometric memoirs that inability to read or write was necessarily an evidence of mental deficiency which should render the individual so affected liable to be segregated for life.

Canon HORSLEY and Mr. THEODORE NEILD also took part in the discussion, and Dr. HYSLOP briefly replied.

## EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

*The Present Position of the Treatment of Plague.—Exhibition of Cases and Specimens.*

A MEETING of this society was held on Jan. 11th, Dr. BYROM BRAMWELL, the President, being in the chair.

Dr. J. C. THOMSON read a paper entitled "The Present Position of the Treatment of Plague." He began by emphasising certain points in reference to the general management of a case of plague. While pneumonic cases, fortunately few in most epidemics, were virulently infectious through the emanations from the lungs, and must be dealt with in hospitals where due precautions against spread of the disease could be adequately provided, the results obtained by the Second Indian Plague Commission (1905–1907) showed that bubonic and septicæmic cases might be safely treated in the wards of ordinary hospitals, or in their own homes, provided that measures against rats and their fleas be taken. Combined methods were recommended for the rapid local extermination of possibly infected rats: traps with baits varying from day to day; poisoning with phosphorus, 2·5 per cent., or with barium carbonate, 25 per cent.; birdlime spread on boards and baited like the traps; and Danysz's virus. For the destruction of fleas a most efficient pulicide in combination with a germicide was a mixture of equal proportions of petrol and cyllin, diluted with water 1 in 200. Contacts—i.e., persons who might presumably have been exposed to the bites of fleas in the circumstances where infection of the patient occurred—should be inoculated with Haffkine's prophylactic, which has maintained its reputation as the safest and most efficient plague prophylactic, though a number of others have in recent years been prepared. As to the question of arrangements for disinfection during the illness, these may be approximately the same as in the case of enteric fever, except in cases of the pneumonic type, which being virulently infective from person to person required the most complete measures possible in this respect. Careful nursing of a case of plague was of the first importance. On account of the marked tendency to heart failure in this disease the recumbent position was essential so long as acute symptoms lasted, and in delirious patients, who were often wildly resistive, had not infrequently to be maintained by mechanical means. Points in reference to the nursing of plague were described, attention being specially directed to close observation of the state of the bladder. Food should be of a bland character, liquid, and given in small quantity frequently, but after acute symptoms subsided the diet might be rapidly improved. Water should be freely at disposal between the feeds, and should be frequently forced on acutely ill or delirious patients. The use of cardiac stimulants should be a routine practice in all cases of plague from the very first. Great prostration occurred as a rule within a few hours from the commencement of the illness, and in the earliest stages the debilitated heart needed support. Some of the symptoms that were apt to prove urgent in plague were next referred to—constipation, diarrhœa, high temperature, headache, delirium, insomnia, hæmorrhage—and the remedies found most useful in Dr. Thomson's experience in Hong-Kong were described. The treatment of the plague bubo had been the subject of much discussion, but the consensus of opinion was against excision of it. A large proportion of the buboes of patients who recover resolved without suppuration. Injections of antiseptics into the bubo were of no value. The point of inoculation of plague should always be looked for, and, if discovered, should be attacked vigorously. Unfortunately, it was rarely to be found, in this according with experimental results in the monkey. But occasionally there might be seen on a limb, below the bubo, a papule with an inflamed base and a clear vesicle at the top, the contents of the vesicle swarming with plague bacilli in pure culture. Destruction of this papule by a thorough deep cauterisation with carbolic acid after crucial incision was usually followed by abortion of the illness and a rapid recovery. The indolent ulcers that sometimes resulted from the buboes and the gangrenous skin areas, so-called carbuncles, occasionally met with, were manifestations of the general depression, and their treatment was on general principles. Convalescence from plague was usually slow, and the profound enfeeblement frequently resulting from the illness, with the mental and other sequelæ that sometimes occur, had to be dealt with as individual cases demanded. Dr. Thomson then proceeded to discuss a number of efforts made to find a specific remedy for plague in the directions of antiseptic drugs, serum-therapy, and organo-therapy. He described his own attempts to introduce carbolic acid into the tissues in sufficient quantity to delay the proliferation of the plague bacillus and allow the natural reaction against the organism time to assert itself. The use of 80 grains a day in a series of 204 cases seemed of little value, the plague hospital mortality being 76·5 per cent., only slightly less than the Hong-Kong average. But in another epidemic 144 grains daily in a series of 143 cases gave a mortality rate of only 36·4 per cent., this result, however, being obtained in the second half of the epidemic when the disease was normally less virulent. In the earlier half of the same epidemic oil of cinnamon had been used, but proved valueless. Further experience in Hong-Kong confirmed Dr. Thomson's belief that carbolic acid, while in no sense a specific remedy, was of undoubted value in the treatment of plague when given in massive doses. Trials made with other antiseptics had been disappointing. The position as regards the serum treatment of plague was pretty much that described in reference to antiseptics. Most unequal results had been obtained by different observers, among different races, in different epidemics. In comparing results it was important to note that European races showed a much larger proportion of recoveries, irrespective of treatment. In a series of 94 cases treated by Dr. Thomson in Hong-Kong with serum supplied by the Pasteur Institute in Paris the mortality was 85 per cent., and further trials gave scarcely better results. In Bombay Choksy, using the same serum, had in a series of 200 cases a mortality of 63·5 per cent., while in 200 control cases the mortality was 74 per cent., showing a gain of 10·5 per cent. On the other hand, in Oporto 140 cases were treated, with a mortality of only 14·78 per cent.; and in Brisbane

56 persons were treated, with a mortality of 44·6 per cent.; 39, with a mortality of 17·2 per cent.; and 65, with a mortality of 13·8 per cent. Various other serums tested by Choksy gave less favourable results than the Yersin-Roux serum of the Pasteur Institute in Paris. Indian experience generally seemed to indicate that case-mortality was but little affected by the use of any serum yet prepared; but the course of the illness was favourably influenced, especially if serum be used on the first day of the illness. As to organo-therapy, the use of adrenalin chloride was advocated by E. N. Thornton from experience in South Africa. It had previously been recommended in India by Bose, and Choksy had used it as a remedy for heart failure in plague. Thornton in a series of 50 cases had a mortality of 26 per cent.; in 936 cases previously recorded the mortality had been 37·4 per cent. The apparent advantage was therefore much the same as that obtained with serum in Bombay. Dr. Thomson summed up the present position of the treatment of plague as an exceedingly unsatisfactory one. In spite of earnest work devoted to it in all parts of the world during the recent pandemic their ability to deal clinically with this very fatal and perplexing disease had advanced but little since the question first in modern times became urgent in the Hong-Kong epidemic of 1894. They had still to place chief reliance on careful nursing and general management as for an acute asthenic fever. For the rest, where fresh serum was available it should be used, together with adrenalin, for advantages it certainly seemed to possess; where serum absolutely fresh was not to be had Dr. Thomson was still prepared to use carbolic acid, giving adrenalin along with it. And meanwhile the hope remained that sooner or later a serum might yet be evolved that would prove really efficient as a plague remedy.—Dr. WILLIAM RUSSELL said that it was most gratifying to the society to have had a communication of this nature from a gentleman who from his own practical experience had all the details both of the disease and of its remedies at his fingers' ends.—The PRESIDENT and Dr. FRANCIS D. BOYD also spoke.

Mr. CHARLES W. CATHCART showed: 1. A girl who showed the Advantage of Re-suture of the Facial Nerve when divided during removal of a parotid tumour. The tumour was deep-seated and the pes anserina was stretched over it. Division of the nerve was not recognised until the patient recovered from the anæsthetic condition. Next day Mr. Cathcart reopened the wound, and the surface was explored with electrodes in order to discover by twitchings of the muscles set up which were the distal extremities of the divided nerves. When found, these were united to the proximal ends, and almost complete recovery took place within three months. 2. A man with a Large Fistulous Opening just above the hyoid bone which was the result of an attempt at suicide by cutting the throat. It was the worst case of cut-throat which Mr. Cathcart had ever seen, the tongue having been almost completely separated from the hyoid bone. Sloughing of the wound took place and the large gap now present was the result. Mr. Cathcart demonstrated some interesting points as to the mode of formation of vowel-sounds, showing that these were really made above the larynx, probably in the situation of the back of the throat or tongue.

Mr. J. M. COTTERILL showed a unique specimen of a Diverticulum of the Cæcum which contained a very large concretion. The specimen was obtained from a man, aged 45 years, who suffered from pronounced toxæmia. The tumour lay rather behind the gall-bladder and was of the hardness of stone, giving on tapping a sound metallic almost in nature.

Dr. A. D. WEBSTER gave a demonstration as to the Value of Exercises on Health.

## EDINBURGH OBSTETRICAL SOCIETY.

*Landry's Paralysis during Pregnancy and the Puerperium.—Achondroplasia and Allied Variations.*

A MEETING of this society was held on Jan. 11th, Dr. F. W. N. HAULTAIN, the President, being in the chair.

Dr. SAMUEL DAVIDSON (Kelso) sent a paper on a case of Landry's Paralysis occurring during Pregnancy and the Puerperium. The patient, who was now 41 years old, had had eight children, seven of whom were now living; she had not had any miscarriages. All her pregnancies and confinements had been normal till the seventh. Towards the end of her seventh pregnancy, about Dec. 15th, 1906, she began to complain of pains in her legs and feet and had considerable difficulty in walking; at the same time there was troublesome vomiting. She was delivered on Jan. 6th, 1907, of a stillborn child. The labour was easy and natural. Three days afterwards she could not move her legs at all and suffered with pains in them. During the next few days the muscles of the trunk and arms became progressively paralysed. She was quite helpless, unable to feed herself or turn in bed, could not move either hand or foot, and had wrist-drop and pointing of the toes. There was no paralysis of the muscles of deglutition or respiration. Retention of the urine occurred during the first week of illness and required the use of the catheter for four months. With the exception of the pain in the feet there was no disorder of the sensation; there were no bed-sores and no electrical changes in the muscles, and not much wasting. In May, 1907, improvement set in, first showing itself in the arms, but the finer movements in the fingers were a very long time in being established. The patient suffered from internal strabismus before her illness, but it became worse during her illness and improved as the paralysis passed off. The patient again became pregnant in September, 1907, and was delivered of a living healthy child in June, 1908. This pregnancy did not make the paralysis any worse, though it may have slightly retarded the progress of her recovery. About September, 1908, she began to walk with the aid of two sticks, and continued to require the help of one stick in walking till a few months ago. Now she had no pain but occasionally felt cramp in her arms and legs. There was apparently only one muscle now remaining paralysed, that being the extensor proprius hallucis on the right side. She was well nursed during her illness. The only medicinal treatment was the administration of arsenic and strychnine after the acute symptoms had passed off. Dr. Davidson was inclined to believe that the cause was probably one of the toxæmias of pregnancy. Only one reference was found, by F. Lenitton, "Landry's Paralysis Complicating Pregnancy," in the *North-Western Lancet*, Minneapolis, vol. xxii., p. 318 (1902).—Remarks were made on the paper by the PRESIDENT and Dr. J. W. BALLANTYNE.

Dr. D. BERRY HART read a paper on Achondroplasia and Allied Variations, illustrated by a series of lantern slides. It expressed the views contained in Dr. Hart's communication to THE LANCET of Jan. 14th, p. 124.—The paper was discussed by Dr. BALLANTYNE, Dr. A. H. F. BARBOUR, Dr. W. FORDYCE, Dr. J. W. SIMPSON, Dr. JAMES RITCHIE, and Dr. A. COWAN GUTHRIE.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF PATHOLOGY.

*Tumours of the Brain.*

A MEETING of this section was held on Dec. 2nd, 1910, Mr. A. H. BENSON, the President, being in the chair.

Dr. T. G. MOORHEAD exhibited two specimens of Cerebral Tumour. The first was from a man, aged 42 years, who came to hospital some months ago complaining of pain in the head, of vomiting, and of difficulty in walking and standing. Five weeks previously he had fallen in the street and hurt his left knee. Previously he had not felt sick in any way. His special difficulty was in steering himself. There was no history of previous disease. He admitted having been a fairly heavy drinker, but nothing more. There was a slight increase of knee-jerks, no ankle clonus, and normal plantar reflexes. When standing he tended to fall backwards and to the right side. Nothing abnormal in the arms except a little incoördination on the right side. No disturbance of sensation. Mr. Benson found that the right optic nerve was in a state of extreme neuritis; no neuritis on the left side. The pupils reacted normally. No nystagmus. Owing to his mental state it was impossible to determine whether there was any hemiopia or not. No other cranial nerve involvement; no trophic or visceral symptoms. He was mentally dull and apathetic. The symptoms pointed to intracranial growth, and they trephined on the right side in the occipital region. Mr. Henry Moore

cut into the dura mater and displayed a cyst which contained about half an ounce of clear, yellowish fluid, epithelial in structure, and probably not malignant. Subsequently the patient improved very much. Symptoms of intracranial pressure again developed. Thinking the cyst might have filled up, they turned down the flap and put a drainage-tube into it. Fluid escaped, but not much. The patient was relieved, but again the symptoms of pressure returned, he became hyperæsthetic, and developed trophic lesions on his heels. They operated in the cerebellar region and found that the cyst did not originate there as they had suspected. The operation relieved the pressure, but the patient died in three or four weeks mainly from cardiac failure. They found in the frontal region of the brain a tumour of about the size of a walnut extending to the base of the frontal lobe; also a very small tumour in the temporal region. In the region of the operation was a definite hernial protrusion, an epithelial tumour apparently taking origin from the ependyma. It was apparently a compound malignant papilloma, corresponding to similar tumours found in the ovary. Ferrier had had a similar case, in which, with a frontal tumour, the symptoms were cerebellar. Dr. Moorhead had exhibited the specimen to emphasise the fact that cerebellar symptoms might be present in frontal tumours. Whether the frontal tumour was a development subsequent to the first operation was undetermined. The second specimen was from a man, aged 30 years, who noticed three weeks before admission that he was suffering from giddiness and failure of sight. Mr. Benson reported intense double optic neuritis, if anything more marked on the left side. There were increased knee-jerks on both sides, slight ankle clonus on the left side, normal plantar reflexes on both sides, marked nystagmus, slight diffused headache, and occasional vomiting. They determined to operate on the left side. Mr. Moore trephined and found evidence of great intracranial tension. The patient did not improve. They had no definite indication pointing to involvement of any other part of the brain. At the post-mortem examination a large tumour was found lying on top and slightly in front of the vermis of the cerebellum, compressing the region of the corpora quadrigemina. They had suspected that it was probably in the neighbourhood of the cerebellum. They had felt that the best thing was to relieve tension as rapidly as possible, and leave exploration for subsequent operation. In future cases of nystagmus, without other localising symptoms, he would be inclined to advise immediate exposure of the cerebellar region.

Dr. GEORGE PEACOCKE read notes on a case of Cerebellar Tumour. The patient, a female, aged 18 years, in December, 1909, had an attack of erythema nodosum; since then she had suffered on and off from headaches. In March, 1910, she had double pleurisy and was admitted to Adelaide Hospital on May 14th. Three weeks before admission she had been complaining of severe headaches, accompanied occasionally by vomiting; was constipated. After admission no headache for five days, then she awoke with severe headache. Pulse 40; pupils widely dilated, and respirations 46 and shallow. She was sweating profusely and was very restless. On May 21st Sir Henry Swanzy reported well-marked optic neuritis in each eye, especially the right. On May 31st her condition was: Knee-jerks well marked on both sides; no ankle clonus; plantar reflex normal; no difference in muscular power of legs; sensation normal; no incoördination; superficial reflexes normal; no loss of power in arms. Respirations between 30 and 40, irregular in time and depth. Eyes: Pupils equal, moderately dilated, respond to light and accommodation; slight nystagmus on extreme turning of eyes to the left, which also caused giddiness and nausea. Headache was paroxysmal, occipital and down the back of neck; most severe on left side. Unsteadiness of gait, tendency to fall backwards, but not to either side. Romberg's sign not present. Vomiting had no relation to food, and occurred frequently some days, others not at all. On June 2nd Mr. Gordon trephined over the left cerebellar lobe. The piece of bone removed was not replaced, and a hernia cerebri subsequently developed. The patient's condition did not materially improve and she gradually became less conscious—paralysis and epileptiform seizures appearing towards the end. She died about six months after the onset of definite brain symptoms. Professor Scott described the tumours found, one in each lateral lobe of the cerebellum. They seemed to have started in the neuroglia, and probably existed for some time as a glioma; later, from some reason, growth became more rapid and cellular, and they became indistinguishable from a sarcoma, which was almost typical at the margins of all three growths. This was associated with a formation of connective tissue, death of the neuroglia cells and some degeneration of the neuroglia fibrils, which with some altered blood from small hæmorrhages formed the sclerosed centre. The margins he looked on as a sarcoma, the particularly cellular type of the left tumour being caused by a very rapid growth, consequent on the altered physical conditions due to the trephining operation.

Dr. HAYES showed a specimen of Tumour of the Pituitary Body through the courtesy of Dr. L. Werner. The patient was an unmarried woman, aged 50 years, with some ocular disturbance. Her symptoms when she was X-rayed were: bitemporal hemianopia, both external and internal ophthalmoplegia, double optic atrophy, but no optic neuritis, no headache or vomiting. Towards the end of her illness she was slightly unsteady on getting out of bed. There were no symptoms suggestive of acromegaly or the typical changes in hands or feet. She was radiographed, and the negative showed considerable absorption of the pituitary fossa, absorption of the anterior clinoid process, as well as the posterior process, also absorption of the floor of the pituitary fossa. A negative showing a normal pituitary body was also exhibited and showed the body to be much smaller. Anterior to the tumour the base of the skull looked normal. He diagnosed tumour of the pituitary body. The patient became gradually worse and was totally blind before she died. She developed, finally, bulbar paralysis. Dr. O'Kelly removed the brain and a large tumour of the pituitary was found. As far as he knew it was the first case in the British Isles of which a diagnosis had been made from an X ray photograph, although it had been done on the continent. The exact histological nature of the case it was difficult to determine, but Professor E. J. McWeeney thought it was of an endothelial nature.—Dr. STOKES drew attention to a paper in the *Johns Hopkins Bulletin* by Harvey Cushing in which was a statement which the specimens put before them that evening had impressed upon him—namely, that brain tumours were extremely common. At the Johns Hopkins Hospital five years ago they had operated on six cases and in the last two years on 150. Five years ago they had not a single success. In the last two years they had actually cured 15 or 16 per cent., and had relieved and sent back to work about 60 per cent. of the remainder. They had about 10 per cent. of deaths soon after operation; not a single hernia cerebri or stitch abscess. Stress was laid on early diagnosis and on the point that the fields of vision for different colours were very early altered. From the number of cases which he had seen recently brain tumour was evidently increasing in Dublin.—Dr. K. E. L. G. GUNN said the fact that in two of the cases exhibited a tumour growth was found present at the necropsy at or close to the seat of the opening, which apparently was not there at the time of the operation, was suggestive that the injury might have something to do with the formation of such a growth.—Dr. A. R. PARSONS said that the specimens shown confirmed Horsley's views as to the value of the information to be obtained from destruction of the optic nerves, and he himself recently had a case of double optic neuritis which confirmed the view.—Dr. W. R. DAWSON said it had been held, though not absolutely proved, that the frontal lobes were the site of the moral faculties, and in many cases destruction or injury of the frontal lobe did interfere with the moral character. It was in the frontal region that chronic alcoholism was found to exert most of its deleterious influence. It was held some years ago that foreign bodies in the interior of the brain produced their effects by the extreme local anæmia caused. Where pressure was sudden or rapid the direct pressure itself might result in a seizure; but it was possible to explain epileptoid seizures by means of the extraordinary localised anæmia which they produced.—Dr. J. A. MATSON, Dr. R. J. ROWLETTE, Mr. F. K. CAHILL, Dr. O'FARRELL, and Dr. EUSTACE discussed the cases.—The PRESIDENT said that most of the cases showed very little alteration in the optic neuritis, but the operations were not performed until the cases were almost *in extremis*. Others with larger experience said that the optic neuritis did subside considerably after a decompression operation.

DR. MOORHEAD, in reply, agreed with Dr. Stokes as to the frequency of intracranial tumours. He was, however, confident that even a larger percentage of cures than the *John Hopkins Bulletin* reported would be effected later on. He did not think the actual irritation likely to produce growth. Nothing very positive could be said on the mechanism by which tumours produced their effects, but it was natural to attribute some of the results to increased tension. He used to assume that it was anæmia that led to epileptiform seizures, but the direct effects of pressure lately had rather impressed him. Hemiplegia in relation to tumours of the Rolandic region was, he thought, common. As to the origin of the tumour in the first case it was impossible to get any information. The original cyst completely disappeared at the necropsy. There was no communication with any of the ventricles of the brain. With regard to urinary symptoms, he had found them put down in the literature as fairly constant, but without any explanation. The second tumour was a psammoma.—DR. HAYES also replied.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this society, held on Jan. 5th, Dr. F. Hinds, the President, being in the chair, Dr. D. G. Hall showed a man with a Malignant Growth at the back of the tongue. The patient, aged 46 years, had come as an outpatient to the hospital complaining of sore throat of two weeks' duration. There was a large excavated ulcer at the back of the mouth, which involved the base of the tongue, the soft palate, and the tonsil. It had a hard edge, and there was in the neck a mass of hard glands, which latter the patient had noticed for three months. It was too late to think of any surgical procedure. Dr. Hall remarked that this was a case, only too common, in which the patient discovered that he had cancer only when it was too late to operate.—Dr. L. A. Parry read, for Mr. J. Lawrence Hamilton, a short note on Dogs and Tuberculosis. He contended that where dogs had eaten or drunk tuberculous matter and subsequently scattered their dejecta wholesale on public footpaths this might possibly be one of the means by which tuberculous disease among men and other domesticated animals was propagated and diffused.—Mr. A. J. Martineau read notes of a case of Hæmorrhage from the Tonsil in a young married woman. She had an attack of acute follicular tonsillitis, which quite cleared up, but was followed by severe bleeding from the left tonsil, recurring the next day, though not so badly. On the following day another attack was so severe that she fainted. She was supposed to have lost at least two pints of blood. When the throat was examined the left tonsil was seen to project across the pharynx to meet the opposite tonsil, which was only moderately swollen. Slight bleeding was going on, the blood being rather bright and appearing to come from the upper and back part of the tonsil. The next day the tonsil was removed with the guillotine, and in doing this a cavity filled with blood-clot which had displaced the tonsil from its bed was exposed. The hæmorrhage did not recur. Mr. Martineau also read notes of a fatal case of Otitis, in which the question of delayed chloroform poisoning arose. The patient was a young woman, aged 18 years, who had a mild attack of measles, followed a few weeks later by an attack of otitis. Earache became severe, and Mr. Martineau decided to incise the membrane, and to follow this the next day by a radical mastoid operation, if the symptoms were not relieved. An anæsthetic was given and the membrane incised, but the next day she was still very ill, with a temperature of 103° F., restlessness, and delirium. A convulsion followed. Delayed chloroform poisoning was suspected. In favour of this view were great restlessness, sighing respiration, and a sweet odour of the breath. The urine, however, did not give any reaction for acetone. There was no localising symptom of meningitis. She was given bicarbonate of soda by the mouth and rectum, but in the night she had another convulsion, and her temperature was 106·4°. She was better next day and partly conscious. She gradually got worse mentally and talked incessantly, the back of the neck became stiff, and she had occasional squint. She passed into a state of coma and died a few days later. Mr. Martineau pointed out that if delayed chloroform poisoning was liable to be confused with meningitis another terror had been added to the diagnosis of this disease. He personally regarded the case as one of meningitis.—Dr. Hall and Dr. H. Galt read clinical and bacteriological notes on a recent series of cases of Enteric Fever admitted to the Sussex County Hospital. An attempt was made to show that the Widal reaction might have a prognostic as well as a diagnostic value. Of three cases that ended fatally, in two the reaction was negative throughout, although typical typhoid ulcers were found post mortem; in the third case the reaction was positive only the day before death. In one patient the presence of enteric fever was unsuspected until the admission of her brother to hospital. The symptoms had been masked by a coexistent chorea and acute endocarditis. The brother was sent into hospital as a case of perforation, but a white cell count showed only 2700, and he recovered without operation. On his discharge from hospital he was notified to the medical officer of health as a carrier, but no further examination or treatment was permitted by the parents. In one case the onset was sudden, with a temperature of 104°, sore-throat, and inflammation of the glands of the neck. There was a dull red rash over the neck and buttocks for the first two days, and later an eruption of rose spots. One of the fatal cases was the subject of mitral stenosis of old standing. Acute endocarditis supervened on the diseased valve. In this patient and one other the immediate cause of death was intestinal hæmorrhage.

# Reviews and Notices of Books.

*The Diseases of China, including Formosa and Korea.* By W. HAMILTON JEFFERYS, A.M., M.D., Professor of Surgery, St. John's University, Shanghai; and JAMES L. MAXWELL, M.D. Lond., Medical Missionary in Formosa. With 5 coloured plates, 11 nosographical maps, and 352 illustrations. London: John Bale, Sons, and Danielsson, Limited. Pp. xvi.-720. Price 25*s.* net.

AMONGST the numerous treatises on tropical diseases that have enriched our language of late years no work on those of China has appeared. This omission the authors, who have worked in that country now for a long period of time, have rectified, and a perusal of their book will show how well they have done it. Their aim has been to present to medical men working in China a concise account of the special diseases that they will meet with in their own practice in that empire. The work is illustrated largely by photographs of disease conditions amongst the Chinese, the majority of which have never before been published. Again, special references to the modification of the tropical diseases met with, as brought about by the environment in China, are detailed, so that the student has under his hand a thoroughly trustworthy account of the morbific conditions met with in this interesting portion of the globe.

The work opens with the conditions of practice in China in which we read of its various modes, the Pharmacopœia of China, and its native surgery, amongst other points. Then follows an account of the nosography of the country, after which we come to the consideration of the various diseases. An excellent account is given of plague in all its respects. This article should be of special interest to us in England at the present moment, because the disease has now shown itself to us here, while there is an epidemic just declaring itself in China. In their remarks on enteric fever the authors show, as is the case in the Punjab, that the typical chart is the exception rather than the rule. They wisely lay down the necessity of examining the blood in all cases of fever in the tropics lasting for more than a day or two. Rose spots are usually absent in China, and here again there is a similarity to many cases occurring in India. In the medical treatment salol is stated to be the least harmful depressant amongst the antipyretics. The authors apparently have had no experience of that excellent drug—oil of turpentine—advocated by Sir Robert Simon of Birmingham. In the treatment of cholera, as regards prophylaxis, stress is laid upon the exclusion of flies from the house; we do not

find any mention of inoculation, which has proved so successful according to the results obtained by Haffkine in India. Nor does the method of treating the wells by permanganate of potassium, also of extreme advantage in India, appear to have come under the experience of the authors. Opium is not recommended, we are glad to see, to be given by the mouth; when given, it should be administered hypodermically, as morphia with atropine. With respect to the injection of saline solution, the researches of Rogers, with the good results obtained, are worthy of mention in a second edition. A very good recommendation is that of an ordinary quart size of Thermos flask for keeping the infusion at a constant temperature.

In their remarks on leprosy the authors do not seem, as has been the case with many others, to have found much benefit from nastin in the treatment of this affection. A very exhaustive chapter is accorded to the subject of malaria, this being, indeed, one of the best sections of the work. Then follow the subjects of blackwater fever, kala-azar, and yaws, concluding the section on the protozoal diseases. With regard to yaws we should like to have known the opinion of the authors concerning its supposed relationship to syphilis.

Next are considered the diseases caused by metazoal parasites. Here the student of tropical affections will find a very valuable exposition, as China is pre-eminently the country wherein these diseases are rife. Those due to the parasites of the circulatory system, of the lungs, and of the alimentary canal and liver all receive due attention. This section concludes with a list of the metazoal parasites found in China, illustrated by beautiful drawings, and from this list one can judge what an unfortunate wealth of material exists in this country. Accounts of the diseases of the alimentary canal, of the liver and spleen, and of the nervous system follow. In the treatment of sprue santonin is held to be the only drug worth serious consideration. This remedy has been tried at the Seamen's Hospital, Albert Docks, but without any good results. It would, however, appear that santonin is of use at the commencement of the affection, and this may account for its ill-success at our home institution, as the cases therein admitted have already had the disease for some period.

Amongst the remaining chapters of this valuable work is an excellent one on the undifferentiated fevers, in which are described glandular fever, seven-day fever, urticarial fever, double continued fever, and place fevers. The work concludes with the surgical affections of China and their operative treatment, and with some remarks on hospitals and hospital construction. To this is subjoined an excellent account of the laboratory methods employed for the examination of the blood and fæces.

In concluding this brief review we cordially congratulate the authors on their treatise, which must surely prove of exceptional value to the practitioner of medicine in China.

---

*A Text-Book of General Bacteriology.* By WILLIAM DODGE FROST, Associate Professor of Bacteriology in the University of Wisconsin; and EUGENE FRANKLIN M. CAMPBELL, Professor of Bacteriology in the Ohio State University. Illustrated. New York: The Macmillan Company. 1910. Pp. 340. Price 7*s.* net.

THE early text-books on bacteriology were able, owing to the limited extent of our knowledge, to take a general survey of the whole subject. The modern text-book has been forced, on account of the immense growth of the science, to treat it from the point of view of the specialist, whether he be pathologist, agriculturist, or technician. As a result, the general principles which underlie and link together the several special aspects from which bacteriology may be viewed are prone to be ignored by the student, and there can be no doubt that a book dealing with these general principles and written from the point of view of the biologist rather than from that of the pathologist or other specialist is wanted. It is to fill this want that the present book has been written, and it will no doubt prove very useful, as it presents knowledge acquired during recent years which is often crowded out of the special treatises. Such a work is not necessarily of an elementary character and certainly calls for much wide and accurate knowledge on the part of its writers. The headings of the various parts into which the book is divided—morphology, methods of study, taxonomy (that department of natural history which treats of the laws and principles of classification), general physiology, biology of special groups, and distribution—suffice to show the scope of the work.

It is not necessary to review in detail the several sections. The portions which deal with general physiology and the biology of special groups are perhaps the most important and best treated. There is occasionally some uncertainty as to the exact intention of the book; such uncertainty is seen in the section on the relation to environment, where a general discussion on disinfectants passes into a detailed description of the practical use of formaldehyde, though in another part of the book, quite properly, the student is referred for details as to culture media to a laboratory manual. Any author who wishes to write clearly and decidedly about the chemical products of micro-organisms must be dogmatic, so contradictory and scanty is our knowledge, and on this ground we cannot complain that the term "zymogenic" is arbitrarily restricted to those bacteria which produce amylolytic enzymes and the term "fermentation" to the decomposition of carbohydrates, but if a similar courage had been employed in dealing with putrefaction it would have tended to clearness. There is some repetition in different sections of the book and not infrequently on the same page. Possibly the repetition and the uncertainty of object may be due to the rather hasty preparation in book form of what appears to have been the subject-matter of a course of lectures. There is evidence of haste in the rather numerous slips and misprints.

The book will certainly prove of service, and the slight blemishes can be easily removed when a second edition is called for. The type and general appearance of the book are good.

---

*Pellagra.* By Dr. A. MARIE, Physician to the Asylums Department of the Seine; Director of the Laboratory of Pathological Psychology, École des Hautes Études, Paris; Editor-in-chief, *Archives de Neurologie.* Authorised translation from the French by C. H. LAVINDER, M.D., Passed Assistant Surgeon U.S. Public Health and Marine Hospital Service, and J. W. BABCOCK, M.D., Medical Superintendent, State Hospital for the Insane, Columbia, South Carolina. With 19 illustrations and 4 charts. Columbia: State Company Publishers. 1910. Pp. 434.

THE translators have added some useful chapters to the original work, have contributed some excellent illustrations of the skin lesions taken from photographs of patients in Cairo, Italy, Illinois, and South Carolina, and have provided two bibliographies, one of works written in English, and another, which does not profess to be complete, of contributions to the subject in foreign languages.

It is not too much to say that the work now before us is a very valuable aid to anyone wishing to obtain an elementary grasp of the subject. The list of American references shows very clearly the interest which has been awakened in pellagra in the United States since 1907, for four of the pages are sufficient to enumerate the publications in the English language dating from 1791 to 1906, while 13 are required for the remaining four years. One of the earliest references is to an article in THE LANCET which appeared 84 years ago.[1]

[1] THE LANCET, 1826-7, vol. xi., pp. 476-478.

Dr. Marie's book appeared in Paris in 1908, and is abridged from Professor C. Lombroso's classical treatise on pellagra. The present work is prefaced by two introductory preludes by Lombroso, the latter of which was only received by the translators shortly before the death of the professor. The first mention of pellagra in American literature seems to have been in 1864, when Dr. J. P. Gray published a case occurring in a lunatic. Other cases were reported occasionally, but were not officially recognised until 1907, when an outbreak in an asylum was reported upon. Two pellagra conferences have been held in Columbia, and the most recent statistics show that in the United States pellagra exists, or is suspected to exist, in 33 States, that the number of cases in that country is about 3000, and that a total of 5000 individuals have become pellagrous during the last five years. Dr. Marie, a true disciple of Lombroso, devotes several pages to the discussion of spoiled maize as the cause of pellagra, but the translators, one of whom had the opportunity of coöperating with Dr. L. Sambon last year in Italy, when he was working there as the representative of the Pellagra Investigation Committee formed in London last year (*vide* THE LANCET, Feb. 10th, 1910, p. 451), are anxious that American readers should preserve a judicial mental attitude with regard to the etiology of the disease. They by no means accept the dominant dogmatism that spoiled corn is responsible for the causation of pellagra. The details of the theory that some unknown protozoon, insect-borne, probably by Simulium reptans, will be discovered to be the cause have been furnished by Dr. Sambon, and the translators have these in their mind, though sum up by saying that the belief that the disease is in some way connected with the use of corn as an article of food is so universal as to render its rejection well-nigh impossible except in the face of demonstrative proof to the contrary. "Sambon's idea," they say, "rests only on an argument by analogy, and is at present little more than a suggestion, but a highly interesting one. It may possibly lead to important developments at the hands of investigators." They quote the opinions of two entomologists in Washington, who believe that at present there is no apparent connexion in the Southern States between pellagra and the simulium. Dr. Marie, who has studied the disease in Italy and Egypt, finds that the psychic phenomena may include irritability, loss of memory, obstinate mutism, melancholia, systematised delusions, fleeting hallucinations, sitophobia, or hydromania. He believes in the existence of hereditary pellagra, of which he has seen instances in Italy. The chapters on pathological anatomy and treatment are mostly abridged from the writings of others.

This book ought to be in every medical library.

---

*Studies in Immunity.* By Professor PAUL EHRLICH, Privy Councillor and Director of the Royal Institute for Experimental Therapy, Frankfort, Germany; and his Collaborators. Collected and translated by Dr. CHARLES BOLDUAN, Bacteriologist, Research Laboratory, Department of Health, City of New York. Second edition, revised and enlarged. New York: John Wiley and Sons; London: Chapman and Hall, Limited. 1910. Pp. 712. Price $6.

THE appearance of a second edition of the translation of Ehrlich's "Studies in Immunity" is a welcome sign of the interest taken in this field of research—the most fascinating perhaps of modern developments of pathology. The theory put forward by Ehrlich to explain the phenomena still holds the field as the most intelligible account of this difficult subject; and while some observations—notably those with regard to the quantitative relations holding between the two bodies, amboceptor and complement, which take part in such reactions as hæmolysis—are difficult to reconcile with the doctrine, yet it has shown itself extraordinarily flexible and adaptable to a multitude of phenomena. It has proved above all, as we previously noted, a fertile hypothesis, suggesting new trains of experimental research and leading to extension of knowledge.

Most of the present book is the same as the former edition which we reviewed in the year 1906, and does not therefore need further notice here. Eight new chapters have, however, been added in this edition. The first of these, by Dr. Max Neisser, deals with the multiplicity of antibodies occurring in normal serum, the experimental evidence adduced being the action of normal rabbit serum on different bacteria and the possibility of removing the bodies active against any particular species by addition of the appropriate bacterium, while the potency against other germs is left intact. A second, by Dr. J. Morgenroth, is devoted to the binding of hæmolytic amboceptors, and shows that if corpuscles are sensitised with an excess of amboceptors, some of the latter may, on addition of more corpuscles, leave their first attachment and adhere to the latter. A chapter by Dr. Hans Sachs deals with the joint action of normal and immune amboceptors in hæmolysis and combats the views put forward by Bordet and Gay, and a second by the same writer discusses the power of normal serum to deflect complement, being also directed against Gay, who is stated to have been guilty of a grave experimental error. Dr. Sachs and Dr. J. Bauer write at considerable length on the joint action of several amboceptors in hæmolysis and their relation to the complements, and Dr. C. H. Browning treats of anti-amboceptors. Dr. R. Otto and Dr. Sachs discuss the dissociation of toxin and antitoxin, especially the curious "paradoxical phenomenon" discovered by Behring, but while confirming the truth of the observation in the case of several different toxins they fail to give an explanation.

The most interesting chapter of all to the general reader is perhaps the last, in which is contained Ehrlich's Nobel lecture on the Partial Functions of Cells. In it the author applies his "side-chain" hypothesis to explain certain phenomena of increased resistance offered by particular races of trypanosomes to the action of poisons. He suggests that immunity may result in some cases from disappearance of all the receptors capable of anchoring a poison. He also believes that the death of a parasite is brought about by the occupation of all its nutrient receptors by some antibody, so that it can no longer obtain nourishment from its surrounding medium. He states, finally, that by means of the remedy, arsenophenylglycin, it is possible to kill off any trypanosome in any animal, presumably including man—a triumph of therapeutics, if it is confirmed.

This edition has the great advantage over the former that it is furnished with an index. There are a good many misprints in the new chapters, such as "diagonosis," "sreum," "ilght," "stongly," and so forth; the curious idiom "(Gay) believes to have furnished ....." for "believes that he has furnished," occurs more than once. We do not recollect meeting it elsewhere in American books; it certainly is not English.

---

*Otitic Cerebellar Abscess.* By Dr. HEINRICH NEUMANN of Vienna. Translated by RICHARD LAKE, F.R.C.S. Eng. London: H. K. Lewis. 1909. Pp. 156. Price 4*s*.

THIS little monograph reaches that high standard which a work coming from the pen of so eminent a continental authority as Dr. Neumann would lead us to expect. After an opening section on statistics, which are very fully dealt with, comes one of the best in the book on etiology and pathological anatomy. The various paths of infection are discussed, and an excellent and up-to-date account is given of the bacteriology of cerebellar abscess, including the types

of abscesses resulting from different organisms. Symptomatology is admirably dealt with under the three headings of focal symptoms, general symptoms, and remote effects. In the first of these the question of nystagmus is extensively gone into, and a description is given of the results obtained on functional examination of the labyrinth on irrigation with hot and cold water in cases of labyrinthitis and cerebellar abscess. The next three sections describe the initial, manifest, and terminal stages of a case of cerebellar abscess.

Sections VII. and VIII. are devoted to diagnosis and differential diagnosis respectively. The great difficulty often experienced in diagnosing cerebellar abscess is pointed out, and stress is laid on the importance of performing lumbar puncture as a means of obtaining information as to the character of the cerebral changes. Dr. Neumann states that in his collection of 67 cases in which lumbar puncture was performed 42 gave positive and 25 negative results. Prognosis is shortly and efficiently dealt with. In the section on operation on cerebellar abscess Dr. Neumann commences by indicating the two methods of procedure—viz., operating from the skull and from the middle ear; the former he justly condemns, except in very urgent cases, on the grounds that the abscess is difficult to find and that the primary focus of suppuration is not extirpated. Various modifications for opening the posterior fossa are mentioned, and the method employed by the author is given at some length. We notice Dr. Neumann's advocacy of digital examination in cerebellar abscess, a method with which we do not think many English surgeons will agree. A short section on after-treatment follows, and the remaining 84 pages—more than half the book—are devoted to "Details of Cases," taken from various sources, continental, English, and American.

Mr. Lake is to be congratulated both on his choice of the work and the translation he has made. The book reads as if it were originally written in English.

---

*Nutrition and Dietetics: a Manual for Students of Medicine, for Trained Nurses, and for Dietitians in Hospitals and other Institutions.* By WINFIELD S. HALL, Ph.D., M.D., Professor of Physiology, Northwestern University Medical School, &c. London and New York: D. Appleton and Co. 1910. Pp. 315. Price 7*s.* 6*d.* net.

WE learn from the preface that this book embodies the author's teaching to nurses and students. The book is therefore elementary in character, but it is simply and clearly written and, as a rule, practical in the advice given. After a few pages on the needs of the body and on the natural foods prepared by nature for young animals, the writer proceeds to a definition of food and a classification of foods and food-stuffs. Next follows a section on digestion, assimilation, and excretion; then one on diet in health; and finally, a discussion of diet in disease in general and in special diseases in particular. In the appendices are given a few recipes for invalid preparations, and directions for some simple experiments to illustrate the principles involved in feeding. In the body of the book the influence of Chittenden's researches is manifest. We doubt whether students in this country would be content with the diet here prescribed for their needs: for breakfast a portion of oatmeal, with sugar and cream, two slices of toast, a cup of cereal coffee, and a bunch of grapes; for lunch soup, bread and butter, fruit, cake, and a glass of milk; for dinner meat and two vegetables, bread-and-butter, fruit, and rice pudding. Probably they would feel entitled to the "football player's" allowance, in which a couple of eggs are added to the above breakfast and two lamb chops to the lunch. It seems difficult for authors to maintain a scientific attitude in discussing the use of alcoholic beverages. Here we find beer and cider classed as "intoxicants" and put in a separate class from "beverages," such as tea and coffee, although the latter in excess may be toxic and the former in moderation do not intoxicate. Further, alcohol is termed a "pseudo-food," since, although it is capable of raising body-temperature by its combustion, its action as a vaso-dilatator causes loss of heat. Presumably alcohol *plus* a great coat would constitute a food.

---

*Enzyklopädie der Mikroskopischen Technik. (Encyclopædia of Microscopical Manipulation.)* Edited by Professor PAUL EHRLICH, Dr. RUDOLF KRAUSE, Professor MAX MOSSE, Professor HEINRICH ROSIN, and the late Professor KARL WEIGERT. Second edition. Berlin and Vienna: Urban und Schwarzenberg. 1910. Vol. I.: A–K, pp. 800, with 56 illustrations. Vol. II.: L–Z, pp. 680, with 111 illustrations. Price of the two volumes, 50 marks.

THE microscopical investigation of the structure and functions of animals and plants is a subject sufficiently extensive to fill many volumes, but by judicious selection the editors of the present work have given an adequate account of the most useful methods and appliances in about 1500 pages. Professor Ehrlich, his co-editors, and the numerous contributors whose names appear on the title-page have evidently spared no pains as authors and compilers, and it may be safely predicted that this reissue of their encyclopædia, embodying as it does the principal advances that have been made during the last seven years, will immediately become a standard work of reference.

Of the longer articles in the first volume mention may be made of those on Blood and Blood Parasites (46 pages). Celloidin and its Use for Embedding and other Purposes (28 pages), Chromic Acid and many other Chromium Compounds (18 pages), Experimental Embryology and Embryological Technique (97 pages), Stains and Staining (32 pages), Fixation (12 pages), Formaldehyde (14 pages), Freezing Methods (12 pages), Gold in Microscopy (19 pages), Golgi's Methods (32 pages), Skin (12 pages), Injection of Blood Vessels and Lymph Vessels (70 pages), and Bones, Teeth, and Cartilage (70 pages). In the second volume there are similarly elaborate separate articles on the Examination of Living Objects and Fresh Tissues; on Maceration; on Methylene Blue; on Micrometers, Micrometry, and Micrometer Screws; on Microphotography; on Microscopes; on Lamps; on Microspectroscopy; on Microtomes; on the Nervous System; on Osmiumtetroxide; on Paraffin and its Use for Embedding and other Purposes; on Plague; on the Projection of Microscopic Images; on Protozoa; on the Reconstruction of Specimens from Sections; on the Spirochæta of Syphilis; on the Tubercle Bacillus; on Artificial Digestion; on Widal's Reaction; on Worms; and on Drawing Microscopic Objects. These few selections from hundreds of articles, many of them necessarily short, will suffice to show the practical nature of the information conveyed in these two volumes.

---

*Diagnosis and Treatment of Diseases of Women.* By HARRY STURGEON CROSSEN, M.D., Professor of Clinical Gynæcology, Washington University, Gynæcologist to Washington University Hospital, and Director of the Gynæcological Clinic. Second edition, revised and enlarged. With 744 illustrations. London: George Keener and Co. 1910. Pp. 1025. Price 25*s.* net.

IN our notice of the first edition[1] we called attention to the many merits of this book. It deals almost entirely with diagnosis and treatment, and that it does this very fully is evident when we see that the total number of pages is 1025, an increase of over 200 on the first edition. The special feature of this work—namely, the illustrations—has been considerably added to in the present edition. They now number 744 and are excellently reproduced. The author has done his work well, if at somewhat too great

[1] THE LANCET May 2nd, 1908, p. 1281.

length, but there is a great deal of very useful information given, and several subjects are considered in a much fuller manner than is usual in the ordinary text-books of gynæcology.

Of special interest is the section on foreign bodies left in the abdomen, and the very useful method is adopted by Dr. Crossen of obviating such an accident by using long strips of gauze folded up and contained within a linen bag, from which they are withdrawn as required during the operation. The strips are of such a length that it is physically impossible for one to be left in the abdomen, and any such accident is further prevented by the extremity of each strip being fixed to the bottom of the linen bag containing it. For many years certain English gynæcologists have used with the same object gauze rolls too long to be lost in the abdomen if they are properly used, that is if they are gradually unrolled as each successive portion becomes soiled, being also never cut in any circumstances. But that it is possible to leave even a gauze roll 2 yards long and 6 inches wide in the abdomen if it is used improperly and introduced unrolled is unfortunately a fact. We think that Dr. Crossen's method of using a gauze bag to contain the rolls is a very good one and worthy of imitation. That the list he gives of foreign bodies left in the abdomen is far from complete we are sure, since without doubt the majority of these cases are never published.

The section dealing with medico-legal points in connexion with gynæcological cases has been amplified and a number of interesting cases are cited in which legal action has been taken. In selecting illustrations from other authors Dr. Crossen has not exercised the care he might in making sure that the legend is in all cases correct. For example, in Fig. 342, labelled mucous polypi of the cervix, four, and, we think, five, of the wax models do not represent mucous polypi at all. The common error of Gärtner for Gartner we notice in several places.

---

*Physical Examination and Diagnostic Anatomy.* By CHARLES B. SLADE, M.D., Chief of Clinic in General Medicine and Instructor in Physical Diagnosis in the University and Bellevue Hospital Medical College, New York. With 36 figures in the text. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 146. Price 6*s.* net.

OF the 146 pages included in this work 10 at the end are devoted to the index and 10 at the beginning to the table of contents and the preface. Of the 36 illustrations in the text, some of which, by the way, are sadly out of drawing, several are so often repeated that in reality 25 different drawings alone exist, and one of these merely depicts a stethoscope. For the rest the text is well spaced and the type large and distinct, and therefore the subject matter of the book is not unduly full. Yet even considering the brevity of the book it conveys the impression, when its reading is completed, that there is a good deal less in it than, judging from the title, we might have expected to find.

The book is intended to be a text-book of physical examination, and a compendium of "diagnostic anatomy"—or the anatomy that should be at the command of the physician to aid him in carrying out the examination of his patients and determining the localisation of their diseases. In writing such a work it may be said with truth that the author designed to cater for a real need. A Medical Anatomy, as distinct from a Surgical Anatomy, is wanted; but the present volume does not appear to meet the want.

The author wastes space in introducing subjects of which he has nothing to tell the student save that they are not subjects to be learned from books, and even on points where book-teaching may be quite definite a certain obscurity of style makes his directions somewhat difficult to follow. For instance, the student is told concerning the use of the stethoscope that "there will be occasions when it is necessary to auscultate and a stethoscope is not at hand. The condition of the subject in some cases and in others the dictates of modesty will demand the use of the stethoscope through all of auscultation." Other passages could be quoted as, or even more, involved, and the description of the inspiratory sound is given in one complex sentence containing no less than 75 words. We do not want to be flippant, but the word-painting of the description is not half so effective in producing the impression of the inspiratory sound as is the result of the effort to read the sentence aloud. Such a phrase as "there is a crackling fremitus detected if we mash under our fingers soft tissues" seems to us to imply that the American use of words is not the same as ours; but the transatlantic origin of the book cannot excuse "calumnæ carnæ, and chordeæ tendinæ" (p. 100). Some other curious passages hardly come under the heading of being imperfect through mere complexity: for instance, of splashing sounds the author says: "They may therefore arise intrapleural or intrapulmonary, as well as in the hollow abdominal viscera."

---

## LIBRARY TABLE.

*Hypnotism and Treatment by Suggestion.* By J. MILNE BRAMWELL, M.B., C.M.Edin. London: Cassell and Company, 1910. Pp. 216. Price 5*s.* net.—This is one of the volumes of Messrs. Cassell's "Modern Methods of Treatment" series, and it can confidently be recommended to all who in the course of their professional work are confronted with cases of functional nervous disease that seem to resist ordinary therapeutic measures. The whole book is pervaded by an atmosphere of common sense, preparing us for the good results claimed by the author and described by him in detail. He repeatedly and explicitly states that every stage of the so-called hypnotic condition is a conscious one, and that by hypnosis is not meant a condition resembling sleep, but one of increased suggestibility, and that the various phenomena have resulted from the suggestions made to the patient while in this state. Dr. Bramwell affirms that the whole object of suggestive treatment ought to be the development of the patient's own will power and of his control of his own organism. His long experience leads him to say that possibly the most important thing is not so much the method as the man behind the method, and it would be interesting if he, or someone of experience in these paths of therapeutics, would try to express scientifically just wherein the differences between the successful and the unsuccessful practitioner consist.

*A Manual of Medical Exercises.* By PERCY G. LEWIS, M.D. Brux., Honorary Medical Officer to the Victoria Hospital, and Surgeon to St. Andrew's Convalescent Home, Folkestone. Second edition. Illustrated. London: H. K. Lewis. 1910. Pp. 66. Price 1*s.* 6*d.*—The object of this little book is to form a kind of materia medica of exercises from which can be prescribed the special exercises each patient is required to perform by simply noting down the numbers instead of writing the exercise out in full. All the exercises detailed are meant to be performed with slowness, ease, and grace, without jerking or holding the breath. No exercise is to be continued after the first feeling of fatigue is induced. The book is divided into four parts: Part I. deals with home exercises; Part II. comprises exercises for home or gymnasium; Part III., gymnasium exercises alone; and Part IV., respiratory exercises. From increased experience, the author states he is sure that those exercises are the most useful which are performed without apparatus. This book should prove of service to practitioners who find it necessary to prescribe modified courses of physical exercises for patients the tone of whose muscles is at fault and requires

some stimulus to increase the circulation of both blood and lymph.

*The History of St. George's Hospital.* By GEORGE C. PEACHEY. Part II. London: John Bale, Sons, and Danielsson, Limited. 1910. Price 2*s.* 6*d.* net.—This is the second instalment of Mr. Peachey's interesting history of St. George's Hospital, and includes notes upon life in London during the eighteenth century, especially in its bearing on medicine. It commences with a description of London in 1731, a time when English physicians (of whom it was said that they seldom got their bread until they had no teeth with which to eat it) were to be found at Batson's or Child's Coffee House, usually in the morning. The chapter closes with an account of the conversion of Lanesborough House into St. George's Hospital. Lanesborough House, the home of the Lane family, was situated at the corner of the Green Park and Hyde Park, but the neighbourhood, of course, wore a very different aspect from that which it wears to-day, and the author's brief but vivid description of the London of Addison and Steele, Smollett, Fielding, and Hogarth, as well as his incidental references to London of the seventeenth century, form not the least interesting part of the chapter. Included in this part is a reproduction of an engraving of St. George's Hospital by Isaac Watt, about 1736, and a plan of Lanesborough House as it appeared when taken over by the trustees for the hospital in 1733. There is also a pedigree of the Lane family. Publications of this kind do not always receive the support which they deserve, and in the present case it is possible that the medical as well as the lay public may not fully appreciate the extreme interest of the book. It certainly should appeal to all past and present students of St. George's Hospital, but the medical profession generally might like to learn the history of an institution associated for years with men like John Hunter, Edward Jenner, Mathew Baillie, Benjamin Brodie, and Thomas Young.

*Medical Guide to German, Austrian, and Swiss Watering Places.* Edited by HAROLD MORRÉ, M.D. Second edition. Berlin: Eugen Schachtel. 1910. Pp. 153. Price 2*s* 6*d.*—This book contains a description of the principal continental watering-places, with copious illustrations; also an index of morbid conditions that form indications for certain resorts. It may aid the practitioner in selecting a proper destination for those of his patients who are convinced that a foreign excursion is necessary for the restoration of their health and are fortunately able to afford one.

*Vaccine Therapy: Its Administration, Value, and Limitations.* London: Longmans, Green, and Co. 1910. Pp. 216. Price 4*s.* 6*d.*—This is a reprint in book form from the Proceedings of the Royal Society of Medicine of the discussion on Vaccine Therapy which began with an address by Sir Almroth Wright on May 23rd, 1910, and occupied six successive meetings. Sir Almroth Wright's address was published in full in THE LANCET of Sept. 23rd, together with an abstract of the discussion. The republication of the papers in book form will be very useful to those practitioners who desire to render themselves conversant with the present status of vaccine therapy from many view points.

"*Medicus,*" *Guide Annuaire des Étudiants et des Praticiens* (*Médecine, Chirurgie, Odontologie, et Pharmacie*). Par A. ROUZAUD. Préface de M. le Dr. YVON. Paris: 41, Rue des Écoles. Pp. cxliv.-1440. Price 5 fr. (4*s.* 2*d.*)—This book is a continuation of a series of annual guide-books which have appeared for many years. The subject-matter is carefully classified into five parts: (1) Matters relating to the teaching of medicine, pharmacy, and odontology, with programmes of the various competitions for the posts of externe, interne, &c.; the entrance requirements for the military, naval, and colonial medical services; a list of the hospitals, and a plan of the "Assistance Publique" of Paris, insane asylums, learned societies, students' societies, &c.; (2) lists of the faculties of the provincial and colonial medical schools; (3) a directory, both alphabetical and local, of physicians, surgeon-dentists, dentists, and pharmacists; (4) a list of the faculties of the more important foreign medical schools, which is followed by a dictionary of legal medicine by M. Marcel Petit, of the Paris Court of Appeals; and (5) a collection of laws, decrees, and ordinances relating to the practice of medicine and pharmacy, the protection of the public health, sanitary police, public assistance, occupation accidents, health resorts, mineral springs, &c. The book undoubtedly contains much valuable reference matter, though in the section on foreign medical schools we note a number of important omissions as regards Great Britain and the United States. Accompanying the volume is a paper-bound engagement book, "Agenda de Medicus," for the period between Oct. 1st, 1910, and Oct. 1st, 1911, each day having lines for half-hour periods from 8 A.M. to 6.30 P.M.

*Medical Etiquette.* By Dr. GEORGE SURBLED, Professor of Deontology at the Paris Post-Graduate Medical School. Translated from the second French edition by W. P. GRANT, M.B., Ch.B. Vict., M.R.C.S. Eng., L.R.C.P. Lond. With a preface by Sir DYCE DUCKWORTH, Bart., M.D., LL.D. London: Sherratt and Hughes. 1910. Price 5*s.* net.—We agree with Sir Dyce Duckworth's words in his preface that "this work is certainly remarkable as an exposition of the views of an experienced, right-minded physician and Christian," and we join in his recommendation of its study to the medical profession. What is right conduct in one country is right conduct in another, and the fact that the rules of deontology which are sound for France should be sound also for Great Britain is sufficient proof that medical etiquette is not represented by abstruse rules, but is in truth the plan for a broad kind of professional conduct founded on the great maxim of Christianity, "Ye shall do unto others as ye would they should do unto you."

*Human Anatomical Model (Female). A Life-size Reproduction of the Dissections of the Various Parts of the Human Body.* With Descriptive Index by FREDERICK NORMAN, F.R.C.S. Eng., and W. G. STONE, M.D. Oxon., F.R.C.S. Eng. London: Gresham Publishing Co. Price £2 5*s.*—On two stout folding cardboards opening lengthwise is displayed the full-sized figure of a woman. Layer by layer the coverings are turned aside, showing first the superficial, then the deep muscular layers. The internal organs of the abdominal and thoracic cavities in like manner can be turned back, displaying their relations one to another, until finally the skeleton is reached. There is also a detachable portion of the lower abdomen and pelvis in which are displayed the interior of the uterus and its contents at varying stages of pregnancy. The descriptive index is very clear as regards identifying the various organs as they come into view, and the model will prove of assistance to senior students and practitioners who may have occasion to review their anatomy, especially in regard to anatomical relations. It would have been more valuable for beginners if the converse process had been added, by making an alphabetical index of all the parts shown with a reference to the different plates in which they could be found, and perhaps in any further issue of a useful publication the possibility of this addition will be considered.

*Stocks and Shares.* By HARTLEY WITHERS. London: Smith, Elder, and Co. 1910. Pp. 371. Price 7*s.* 6*d.*—Mr. Hartley Withers, an authority on this subject, places on his title page a quotation from "An Essay on Public Credit," written 200 years ago—"I am to speak of what all People are busie about, but not one in Forty understands." It is widely said, and we have reason to believe that there is a good deal of truth in the remark, that there is no class of the community less able to deal advantageously with their savings and

incomes than medical men. As a class medical men are not rich, those with the largest incomes having often unduly heavy expenses as well as very little leisure to think of their own concerns, so that it may be replied to those who criticise our unbusinesslike methods with regard to our savings, that the savings themselves do not in the aggregate amount to much. But to read such a book as this is to learn that the art of sound investing is not beyond either those whose time is very much occupied or those who have little to invest.

*The Chained Titan.* By W. G. HOLE. London: G. Bell and Sons. 1910. Pp. 104. Price 4*s.* 6*d.* net.—Mr. W. G. Hole has produced in the "Chained Titan" what to our mind is a rather remarkable poem. A modern pilgrim, a social worker at home, who is familiar with all the terrible defaults of our present economic conditions, finds himself at a little seaport on the Greek coast and rows out alone to watch the sunset. He is conducted by Hermes to a valley where Chaos is discoursing on the signs of the times to the other gods, finding the resistance of man to the forces of pestilence, plague, and famine growing stronger and the influence of the gods waning. The pilgrim then comes across Prometheus undergoing his perpetual torture and the chained Titan protests against the way in which mundane affairs, as he has learned of them, are conducted He himself had suffered in order to place in the hands of men the opportunities of advancing in the arts of civilisation, but it seemed that as men grew powerful against the paralysing influences of the old gods they became tyrants themselves, the strong grinding down the weak. The representatives of those on whose behalf he speaks debate the subject before him, when Chaos returns; but at this moment the "Eternal Sacrifice" is revealed, and as the pilgrim descends the mountains he passes through forests which thrill with the mysteries of birth and growth. This is a mere outline, mainly in the author's own words, of the tremendous subject-matter of this short poem. In the main it is written in dignified blank verse, but the strand is broken with many graceful stanzas. The book has a peculiar interest to us because it is dedicated to the memory of our late assistant editor, Dr. J. Bart Rous, of whose "rare insight as a critic and perfect loyalty as a friend" the author speaks in acknowledgment of a personal debt.

## JOURNALS AND MAGAZINES.

*The British Journal of Tuberculosis.* Edited by T. N. KELYNACK, M.D. Vict. Vol. V., No. 1, January. London: Baillière, Tindall, and Cox. Single copies, 1*s.* 6*d.*; annual subscription, 5*s.* post free.—This number contains the following articles: 1. A Popular Crusade against Consumption, by Mr. C. H. Garland, giving a brief account of the special appeal of the National Association for the Prevention of Consumption. 2. The Conquest of Tuberculosis, by Dr. David B. Lees, in which reference is made to the method of treatment by inhalation recommended by him. 3. Directions for Living and Sleeping in the Open Air, by Dr. Thomas Spees Carrington, a paper which is full of useful practical hints. 4. Local Effort in the Anti-tuberculosis Campaign, by Mr. Reginald E. Stidolph, giving a short account of the methods employed in the town of Brooklyn to arouse interest in this question by advertising and other means. 5. Some Effects of the Constant Current upon Tubercle Bacilli in Fluids, by Dr. Charles Russ. 6. Impressions of the International Tuberculosis Conference, Brussels, 1910, by Dr. Nathan Raw. Two "critical reviews" are also included, one by Dr. F. Rufenacht Walters on Sanatorium Treatment in Pulmonary Tuberculosis, and another by Dr. Hugh A. Macewen on Milk and Tuberculosis, as well as some general information in regard to institutions for the tuberculous, books, preparations, and appliances.
